Some of these gains are a result of HEW requirements, some the result of Court orders. But most are the result of political power which has accrued from electing people friendly to “Black enlightened self-interest” and by electing Black officials. The number of Black elected officials had grown from about 1,200 in 1969 to 4,500 in 1978, an increase of 280 percent.

CONCLUSION

Thousands of educational positions which would have gone to Black people in the South under a segregated system have been lost for them since desegregation, and the number increases with each report. In the North, East and West, where it has been traditionally hard for minority teachers to be employed, recent gains are being made.

More Blacks are being elected to school boards and, as the population trends change, more systems are gaining Black majorities. As this happens, more Black educators are being hired in decision-making positions in the administration. As more Blacks, other minorities, and other fair-minded persons are placed in these sensitive positions, the opportunities for equal job opportunity in education will increase and hopefully reverse the steady eroding of job opportunities for Blacks which has been going on in the South since 1954.

A STATEMENT ON MULTICULTURAL EDUCATION

In an action reflecting its commitment to alleviating social problems through education, the American Association of Colleges for Teacher Education established the Commission on Multicultural Education. The Commission, formed in the aftermath of the Kent State and Jackson State tragedies, is the outgrowth of the Association’s long history of involvement in building a more effective and humane society through the betterment of teacher education.

The Multicultural Statement is a significant product of the Commission’s work. The Statement, which was adopted officially in November 1972 by the AACTE Board of Directors, was prepared for AACTE, its member institutions, and other centers of higher learning as a guide for addressing the issue of multicultural education.

Commission members caution that the term “multicultural” is not a euphemism for “disadvantaged.” Rather, the Statement encompasses broad ethnic and cultural spheres.

The Statement, a product of Commission interaction with a number of higher education institutions and personnel, is presented here in the interest of improving the quality of society through an increased social awareness on the part of teachers and teacher educators.

Multicultural education is education which values cultural pluralism. Multicultural education rejects the view that schools should seek to melt away cultural differences or the view that schools should merely tolerate cultural pluralism. Instead, multicultural education affirms that schools should be oriented toward the cultural enrichment of all children and youth through programs rooted to the preservation and extension of cultural alternatives. Multicultural education recognizes cultural diversity as a fact of life in American society, and it affirms that this cultural diversity is a valuable resource that should be preserved and extended. It affirms that major education institutions should strive to preserve and enhance cultural pluralism.

To endorse cultural pluralism is to endorse the principle that there is no one model American. To endorse cultural pluralism is to understand and appreciate the differences that exist among the nation’s citizens. It is to see these differences as a positive force in the continuing development of a society which professes a wholesome respect for the intrinsic worth of every individual. Cultural pluralism is more than a temporary accommodation to placate racial and ethnic minorities. It is a concept that aims toward a heightened sense of being and of wholeness of the entire society based on the unique strengths of each of its parts.

Cultural pluralism rejects both assimilation and separatism as ultimate goals. The positive elements of a culturally pluralistic society will be realized only if there is a healthy interaction among the diverse groups which comprise the nation’s citizenry. Such interaction enables all to share in the richness of America’s multicultural heritage. Such interaction provides a means for coping with intercultural tensions that are natural and cannot be avoided in a growing, dynamic
society. To accept cultural pluralism is to recognize that no group lives in a vacuum—that each group exists as part of an interrelated whole.

If cultural pluralism is so basic a quality of our culture, it must become an integral part of the educational process at every level. Education for cultural pluralism includes four major thrusts: (1) the teaching of values which support cultural diversity and individual uniqueness; (2) the encouragement of the qualitative expansion of existing ethnic cultures and their incorporation into the mainstream of American socioeconomic and political life; (3) the support of explorations in alternative and emerging life styles; and (4) the encouragement of multiculturalism, multilingualism, and multidialectism. While schools must insure that all students are assisted in developing their skills to function effectively in society, such a commitment should not imply or permit the denigration of cultural differences.

Educational institutions play a major role in shaping the attitudes and beliefs of the nation’s youth. These institutions bear the heavy task of preparing each generation to assume the rights and responsibilities of adult life. In helping the transition to a society that values cultural pluralism, educational institutions must provide leadership for the development of individual commitment to a social system where individual worth and dignity are fundamental tenets. This provision means that schools and colleges must assure that their total educational process and educational content reflect a commitment to cultural pluralism. In addition, special emphasis programs must be provided where all students are helped to understand that being different connotes neither superiority nor inferiority; programs where students of various social and ethnic backgrounds may learn freely from one another; programs that help different minority students understand who they are, where they are going, and how they can make their contribution to the society in which they live.

Colleges and universities engaged in the preparation of teachers have a central role in the positive development of our culturally pluralistic society. If cultural pluralism is to become an integral part of the educational process, teachers and personnel must be prepared in an environment where the commitment to multicultural education is evident. Evidence of this commitment includes such factors as a faculty and staff of multiethnic and multiracial character, a student body that is representative of the culturally diverse nature of the community being served, and a culturally pluralistic curriculum that accurately represents the diverse multicultural nature of American society.

Multicultural education programs for teachers are more than special courses or special learning experiences grafted onto the standard program. The commitment to cultural pluralism must permeate all areas of the educational experience provided for prospective teachers.

Multicultural education reaches beyond awareness and understanding of cultural differences. More important than the acceptance and support of these differences is the recognition of the right of these different cultures to exist. The goal of cultural pluralism can be achieved only if there is full recognition of cultural differences and an effective educational program that makes cultural equality real and meaningful. The attainment of this goal will bring a richness and quality of life that would be a long step toward realizing the democratic ideals so nobly proclaimed by the founding fathers of this nation.

5.4 Educators’ preparation for cultural and linguistic diversity

A call to action

*Committee on Multicultural Education*

**INTRODUCTION**

The guiding motivation of this policy paper is to provide information about issues surrounding the education of culturally and linguistically diverse (CLD) student populations. Preparation of non-English speakers to survive in English-dominant schools and society is more complex than current policy debates would suggest. Of paramount concern in this paper is the need for teachers who can deliver classroom practice that respects the language and culture of the child, and effective, accommodative, instruction that results in literacy and academic success for second-language learners.

Of equal concern is the context that distinctly favors the assimilation of CLD students. There is little thought given to their rich cultural heritage or the language knowledge they bring to the classroom. At the policy level, this sociopolitical context poses a distinct challenge for future support and development. At the level of praxis, this context threatens efforts to better prepare school educators for the differential learning and transition needs of CLD students.

This paper is arranged in seven sections addressing key terminology, demographics and the achievement gap of CLD students, preparation of public school teachers and administrators, the legal context of teacher preparation for diversity, challenges for the field of education, implications of these challenges, and a call to action.

**TERMINOLOGY OF THE ARENA**

The phrase *culturally and linguistically diverse (CLD) student,* is in our view, most holistically descriptive of a student whose culture and/or language are assets for learning, but nonetheless different, from that of the dominant culture and/or language in American society. Since diversity implies a multi-dimensional learning environment, CLD is also affirmatively descriptive of students who will need *accommodative programming and instruction* to facilitate their cultural and linguistic development within a content-focused learning context.

*Acculturation* defines the process of learning about and living in another/second culture. Individuals who acculturate by *assimilation* are expected to relinquish their own cultural (and sometimes language) identity. Individuals who acculturate by *adaptation* maintain their own cultural heritage (and frequently language) as they learn another.
Accommodation is best understood, according to the notion of mutual (two-way) accommodation (Nieto, 2000). According to Nieto, a belief in one-way accommodation is at the heart of educational strategies which view academically unsuccessful students as culturally deprived or genetically inferior to those who are successful. Mutual accommodation, on the other hand, enables teachers and schools to recognize and build upon the resources and assets that CLD students bring to the school. These resources, when used as a basis for instruction, enhance students’ capacities and abilities to reach academic success.

THE CLD STUDENT

The rapid increase in the CLD student population is changing the fabric of the American classroom. At the same time, the academic achievement gap between these students and others in the schools is widening.

DEMOGRAPHICS

In the last decade, the enrollment of CLD students across the nation has grown at a phenomenal rate of 104.97 percent (National Center of Educational Statistics, NCES, 2002). This growth rate represents an annual increase equal to five times that of the total enrollment in public schools. Today, one in five students throughout the nation comes from a home in which a language other than English is spoken (Crawford, 2000). Additionally, the patterns of migration among CLD students and families within the United States are also changing. The largest and fastest growing CLD student populations continue to concentrate in such coastal states as Florida, California, and Texas. In addition, Midwestern states such as Kansas, Indiana, Iowa, and Nebraska have experienced a dramatic increase in CLD student enrollments over the past two decades. Such increases have exceeded 200 percent per annum in many Midwestern states (NCELA, 2002). This current pattern is a precursor of what is yet to come. Current projections indicate that school-aged children whose first language is not English will constitute an estimated 40 percent of the K-12 age population in the U.S. by the year 2030 (U.S. Census Bureau, 2000). Similarly, if current trends continue, Hispanics will account for 25 percent of the total U.S. population by 2050, and may constitute 33.3 percent of the population by 2100 (U.S. Census Bureau, 2000).

There are over 400 languages currently represented in U.S. schools. Spanish-speaking students comprise 77 percent of the total CLD, K-12 population. Indeed, by far the most common language, other than English, spoken across the nation is Spanish. Other languages representing the remaining 23 percent include Vietnamese, Hmong, Haitian Creole, and Korean, which round out the top five languages spoken by CLD, K12 students in the U.S. Each comprise 1 to 3 percent of this total population (USDE, 2002).

ACHIEVEMENT GAP

Perhaps the central concern regarding CLD students across the nation’s schools is how well they are performing. Unfortunately, national data on the performance of CLD students is very limited. This is most certainly the case with immigrant students. These students constitute one of the fastest growing groups of CLD students, yet sound and valid data on their achievement, school and grade completion rates, and college attendance patterns remain exceptionally limited. Although many reasons account for limited data on CLD student achievement, the number of
CLD students across the nation who are consistently exempted from standardized tests is particularly problematic. Regrettably, as the pressure for test-measured accountability increases, so do the number of CLD students exempted from standardized testing.

What we do know is that CLD students are more likely to drop out of school, have disrupted schooling, lower attendance, and be under-represented in higher level courses in high school. Additionally, among students who score below the 35th percentile on national achievement tests, about 13 percent of the first and third graders and about 6 percent of the lowest achievers in seventh grade are CLD students (NCES, 1999). The drop out rate among these students continues to average over 40 percent, especially where native language-to-English transitions have proven difficult (NCES, 1999). Not surprisingly, the USCCR (1997) found that CLD students, nationally, are three times more likely to be low achievers than high achievers; two times more likely to be at least one grade level behind in school; and four times more likely to drop out than their native-English-speaking peers.

PUBLIC SCHOOL EDUCATORS

Increases in the number of CLD students in U.S. schools are placing greater demands on teacher preparation as well as professional development programs for inservice educators. School educators need support in developing the capacity to provide appropriate and effective instruction for CLD students. According to the National Center of Educational Statistics [NCES] (1997), only 2.5 percent of teachers who teach CLD students hold a degree in either Bilingual or English as a Second Language (ESL) education. States that have the least experience with CLD student populations face the greatest shortage of certified bilingual and (ESL) teachers (AAEE, 2001). Although most CLD students spend the majority of their school day in grade-level classrooms, most teachers in these classrooms have little or no training in the differential learning and development needs of these students. Of the total number of public school teachers across the nation, only 12 percent of teachers who have CLD students in their classrooms have had eight or more hours of professional development specific to the needs of this student population (NCES, 2002). Consequently, few teachers are prepared to provide instruction specifically designed to meet the linguistic, cognitive, academic, and emotional development needs of these students.

As the diversity of the grade-level classroom has increased, the instructional practices to address this diversity have, for many teachers, remained unchanged. They use curricula and materials that do not adequately serve the needs of their CLD learners. According to Short, “The lack of familiarity with their students’ cultures, learning styles, and communication patterns translates into teachers holding negative expectations for students, while inappropriate curricula, assessments, and instructional materials are used with these students, compounding the problem” (Short, 1999, p.107).

LEGAL CONTEXT

The American Association of Colleges for Teacher Education is cognizant of the legal context of teacher preparation for diversity. Multiple court decisions have varied with respect to the support of using the native language of students as the basis for instruction. The landmark Supreme Court case, Lau v. Nichols (1974), ruled that schools had an obligation to adequately prepare CLD students. The justices did not propose solutions due to the fact that they believed that only educators could recommend specific remedies for the education of CLD students. Instead, in Castañeda v. Pickard (1981), the Court stated that programs should
be based on sound educational theory (a theory supported by experts). As a result of the particular theory adopted, using only English for instruction of CLD students was considered acceptable.

Presently, state referenda are changing the mandates on education of CLD students. Short-term English-only instruction in special classes, followed by integration in mainstream classrooms are replacing bilingual education programs. As a result, increasing numbers of unprepared students are entering classes with unprepared teachers. We encourage school educators to acquaint themselves with the legal precedents and mandates for educating CLD students.

Regardless of mandates, educators should be mindful of the words of Justice Douglas in the *Lau v. Nichols* ruling:

> There is no equality of treatment merely by providing students with the same facilities, textbooks, teachers, and curriculum; for students who do not understand English are effectively foreclosed from any meaningful, education.

> Basic English skills are at the very core of what these public schools teach. Imposition of a requirement that, before a child can effectively participate in the education program, he must have already acquired those basic skills is to make a mockery of public education. We know that those who do not understand English are certain to find their classroom experiences wholly incomprehensible and in no way meaningful.

**CHALLENGES**

AACTE recognizes that changing demographics and sociocultural dynamics in public schools require the following:

- teachers/administrators who are better prepared to critically reflect upon the complex dynamics of appropriate accommodations for cultural and linguistic diversity;
- teachers/administrators who advocate for CLD students;
- teachers/administrators who are better prepared to analyze, plan, deliver, and evaluate curriculum and instruction that has been modified and adapted for the differential learning and transition needs of CLD students;
- teachers/administrators who are better prepared to critically evaluate widespread and popular curriculum initiatives, especially pre-packaged curricula, for their applicability with and potential impact on CLD student achievement;
- a curriculum for the preparation of school leaders which prompts them to value and explore both the biographical assets which the CLD student brings to school and the valuable contribution of caregivers, extended family members, and community;
- an enhanced emphasis on advocacy for norm- and criterion-referenced testing in schools which accommodates CLD students at their level of readiness and development, and which is not culturally or linguistically focused to the extent that purposive monitoring and evaluation of process and product gains are precluded.

AACTE must exhibit leadership in these matters. In complex environments of practice, creativity, flexibility, professional development, and collaboration, the American Association of Colleges for Teacher Education seeks to set a new direction, which incorporates these essentials, in a unified effort of proactive leadership.
IMPLICATIONS

As educators, the foundation upon which we practice our craft is rapidly changing. Either we and our respective institutions adjust to meet this change, or the scenario will be one of institutional failure. First, education is the bedrock of the national economy, providing a capable work force that is prepared to participate in a competitive, global market place. Clearly, CLD students now constitute the fastest growing segment of the educational systems in the nation. Concomitantly, this segment demonstrates unacceptably low levels of achievement, coupled with the highest dropout rates. This scenario is fast becoming untenable. What is the purpose of our school systems if the fastest growing segment of their student populations are consistently unable to complete the program, or unable to graduate with a diploma? Qui bono?

Second, the inequitable education of CLD students, as a result of cultural and linguistic differences, is a denial of their civil rights. Currently, these students arrive in the system with needs and differences for which the current system is unprepared. It is the system that must adjust to accommodate these increasingly prevalent differences through differentiated curriculum and instruction. Culturally and linguistically diverse students cannot change their prior socialization in a particular culture or in a particular language. Instead, the system must adjust its practices, build capacity for diversity, and professionally accommodate these differences. Inevitably, the policies and infrastructures of the institution we call schooling must change to accommodate the changing foundation upon which their existence rests. However, change must also begin with the educators who deliver the services of this institution in society. School educators, especially classroom teachers, must be better prepared for the changing fabric of the American classroom.

CALL TO ACTION

AACTE is committed to supporting and moving forward the agenda of ensuring an equitable education for students whose primary language is not English. The Association challenges institutions of higher education to commit to transforming the preparation of educators at all levels to address the changing demographics of American public schools. To this end, AACTE will support partnerships to unite and begin the transformation process in teacher/administrator preparation. Specifically, AACTE invites all member institutions to collaborate in addressing the inclusion of diversity in teacher preparation.

- **Sociocultural:** diversity in teacher preparation must emphasize the sociocultural struggles that CLD students endure. These include learning another culture, acquiring a second language, integrating their world views, performing well in the content areas, and adapting their personal knowledge within the American classroom. Teachers must be prepared to understand and support the acculturation process in a mutually adaptive way, building bridges between the student’s prior cultural knowledge and that of a new cultural environment, including the culture of the school. Teachers must be professionally prepared to explicitly teach the norms, beliefs and expectations of school contexts and society-at-large while affirming the student’s cultural heritage, previous knowledge, and native language proficiency.

This preparation for diversity must begin with the teacher. Teachers must be taught to explore their own socialization in a particular culture as a basis for understanding perspectives on, attitudes toward, and professional responsibility with CLD students and families. They must learn to test the validity of the influence of their own cultural filters upon their own perspectives and actions in practice. Moreover, teachers must be prepared to value, affirm, and maximize the rich cultural heritage that CLD students bring to the school. Ultimately,
teachers must be prepared to acquire the field experiences and learning necessary to understand the acculturation process of students from cultures and languages different than their own.

- **Language**: teacher preparation and professional development for diversity should explore and discuss theories and stages of the second language acquisition (SLA). Teachers need experiences in their preparation that allow them to understand the realities of negotiating academic instruction in another language. Teachers should understand why native language and associated cognitive development are critical to academic success and language acquisition in English. They should incorporate the use of the students’ native language in their teaching, and support language and academic learning objectives as well as literacy development in English. Teachers must be prepared to distinguish social from academic language proficiency, so as to avoid erroneous assumptions about the learner’s preparedness for academic learning. They must be prepared, through well-designed field experiences, to structure environments that promote accumulative, communicative, and constructive language acquisition and literacy development in a second language.

- **Cognitive**: teacher preparation and professional development for diversity must encompass a deep understanding of cognitive development challenges and processes for CLD students. In this regard, prospective teachers must be prepared to differentiate curriculum, instruction, and assessment to accommodate differences in preferred learning styles. Teachers’ field experiences should emphasize the use of context and prior knowledge. Furthermore, teachers must also be prepared to teach students strategies that maximize their cognitive, metacognitive, and social-affective skills in problem solving and critical thinking.

- **Academic**: teacher preparation and professional development for diversity must include an understanding of culturally and linguistically mediated instruction in all content areas. This instruction must be scaffolded and/or sheltered, process and product driven, and grounded in sound theory and methodologies explicitly designed for CLD students. Reductionistic curricula, programs, and instruction may seem sufficient to target social language learning among CLD students, but will not develop the academic language and content learning necessary for successful performance in school.

Ultimately, institutions of higher education must demonstrate critical reflexivity regarding the readiness of their faculties to achieve these benchmarks of teacher preparation and professional development for diversity. Prior socialization is as much an issue for collegiate faculty as it is for grade-level classroom teachers. It requires the capacity to influence perspectives on preparation, attitudes toward the accommodation of diversity, and actions in practice. Accordingly, cross-culturally sensitive professional development and accommodation training are each equally as applicable to college faculty members as they are to public school educators.

Vavrus (2002) suggests that teacher education programs play a crucial role in determining teachers’ attitudes toward diversity and the accommodation of that diversity within their teaching. He strongly recommends that faculty members engage themselves in self-study and internal evaluations to better understand their capacity to infuse diversity issues throughout the curriculum.

Part 5
Commentaries
Although the inclusion of diversity in teacher education has made significant progress, success is not easily measured. Success is difficult to gauge because the field has developed as a series of overlapping “struggles” with peaks and valleys in a changing landscape of different proponents and opponents, political contexts, institutional climates, and demographic changes. Struggles in the teacher education diversity domain continue today as we advocate for our rightful place in the larger fields of educational research and teacher education. We often speak in one united multicultural voice, but many times there are conflicting and competing voices in different conversations. Hence measuring success, in a traditional sense, is difficult if one does not come to grips with the fact that the struggle for inclusion of diversity in teacher education is, and always will be, a contentious battleground that often pits the field against itself as well as against mainstream hegemonic forces. These tensions are reflected in issues related to people, pedagogy, and politics.

**PEOPLE**

The first proponents of diversity in teacher education operated simultaneously as both insiders and outsiders in the field of education. In order to understand the evolution of these insider-outside perspectives, it is necessary to understand the historical context in which diversity emerged in teacher education. According to Banks (1996) the early multicultural education movement started with a small group of African Americans who applied the campus activism they learned in ethnic studies programs, the Civil Rights Movement, and the War Against Vietnam to the field of teacher education. By the early 1970s, these former outsiders were insiders. They were professors in schools and colleges of education who were using their activist strategies of the past to push for the adoption in 1972 of the *No One Model American*, a groundbreaking statement by the American Association for Colleges of Teacher Education (AACTE). This document called for support for cultural diversity, alternative and emerging lifestyles, multiculturalism, and multilingualism. This landmark document was a bold and significant statement for its time.

AACTE’s approval of the *No One Model American* was followed by the adoption of a multicultural education standard by the National Council for the Accreditation of Teacher Education (NCATE). That standard, which became effective in 1979, aimed “to help institutions become more responsive to the human condition, individual cultural integrity, and cultural pluralism in society” (McCormick, 1984, p. 3).

This brief historical context provides the background for the identification of other stakeholders in multicultural teacher education, primarily pre- and in-service teachers in our preparation programs. Research shows that students in such programs are mostly
White females with limited exposure to or experiences with people of color, and often resist their professors’ attempts to teach them about English language learners (ELLs) and issues related to structural inequalities, racism, and White privilege. Sleeter, in this Handbook, states that White preservice teachers are generally fearful both of students of color and of discussing race and racism. Additionally, they tend to rely on the ethnic history and assimilation of their own families, and in turn, assume that the experiences of people of color are or should be the same.

I believe we need to examine the predispositions of students we admit to our programs. One sobering finding in multicultural teacher education that resurfaces continuously is that our programs and courses may have some short-term effect on changing students’ beliefs and attitudes about diversity, but their long-term influence is most likely minimal. It has been my experience that some students enter our programs with prior experiences and predispositions we can build on to help them become more effective multicultural teachers. This group includes: students who are older and have relevant work experiences; students who are parents themselves; students of color; students who have lived, worked, or attended schools in integrated communities; and students with international experiences (e.g. returning Peace Corps volunteers or participants of Study Abroad programs) who have some skills in learning about cultures other than their own.

We need to find ways to identify pre-service teachers who are persistent, open-minded, reflective and complex thinkers, and risk takers. I believe that Diane Goodman (2000) was correct when she concluded that those more likely to be committed to multiculturalism are people of color, people with strong moral and spiritual orientations for social justice, and people who have experienced injustices in our society. Goodman’s conclusion does not bode well for teacher education for diversity. We have to find ways to motivate and educate people from privileged groups and mono-cultural backgrounds to teach in culturally diverse urban schools.

There are also too few preservice teacher candidates of color. Currently, 80 percent of teacher candidates are White (Zumwalt & Craig, 2005). Teachers of color are needed in the profession because their teaching beliefs and instructional practices are related in positive ways to the school achievement of students, especially African American and Latino students, who continue to lag behind their White and Asian counterparts academically. Villegas’ and Davis’ piece in this volume summarizes the research on this topic and concludes that teacher race/ethnicity does influence student learning as well as other important student outcomes like absenteeism, enrollment in advanced courses, and dropout rates.

**PEDAGOGY**

The people involved in and influencing our work in teacher education represent only one aspect of the larger picture. The pedagogy we use to prepare future teachers is a second aspect that needs to be considered. Beverly Armento and I (2001) argue that the demographic changes in today’s schools demand new ways of organizing and implementing instruction. Teachers have to be prepared as culturally responsive educators who understand that students bring a range of cultural and everyday experiences that may differ from their own and certainly differ from the dominant norms of the school.

Teacher education candidates must be taught how to motivate learners and maximize instruction for diverse students. As part of meaningful instruction, teacher educators must consider the language and textbooks used in K-12 schools to represent concepts and ideas, and find better ways to help preservice and inservice teachers connect with the
realities students know and live, in order to help them understand what they are taught. The goal of teacher education for diversity is to produce culturally responsive teachers who:

- are well prepared and competent in their subject matter;
- are advocates for their students;
- teach their students about issues of social justice;
- are change agents and leaders in their schools and in the communities served by those schools;
- understand how to involve their students’ parents;
- know how to teach ELLs and communicate with their parents;
- are problem solvers who search for insight in how culture and ethnicity influence teaching and learning;
- include the history of diverse groups in whatever content area they teach;
- use culturally relevant and student-generated images, examples, and metaphors in their teaching;
- understand students’ learning preferences;
- share ownership of the lessons with students; and
- use a variety of formative and summative assessments to inform their teaching.

POLITICS

Reflecting on the history of diversity in teacher education reveals that our work is as much about politics as it is the people we prepare as teachers and the pedagogy we teach. In fact, AACTE’s *A Call for Action on Educators’ Preparation for Cultural and Linguistic Diversity* (2002) asserted that the inequitable education of culturally and linguistically diverse students is a denial of their basic civil rights. As such, these implications suggest that we, as well as the students we teach, have to be more informed about and active in politics. We have to claim our personal, professional, and political world-views, even when these might conflict with the views held by colleagues who do not embrace the diversity agenda. We must be social reconstructivists committed to the transformation of systems of racism, inequality, and oppression. Too frequently we hesitate to share our beliefs and political stance; however, we need to speak up.

We need to attend to politics at the federal, state, and local levels. Lucas and Grinberg, in their chapter on preparing teachers to teach English Language Learners, point out how political opposition that started in the 1980s decreased the number of bilingual teachers and bilingual programs. State and federal initiatives have circumvented schools and departments of education by offering alternative routes for certification with scant attention to issues of diversity. This growing trend is influenced and supported by the U.S. Department of Education’s current emphasis on mastery of subject matter as the sole criterion for effective teaching.

The No Child Left Behind Act, for example, has made a mockery of the definition of a highly qualified teacher. States can now individually decide what a qualified teacher is. My state, Georgia, defines a highly qualified teacher (with a full not temporary license) as a person who holds a bachelor’s degree in almost any subject and passes PRAXIS I and II. These newly proclaimed “highly qualified” teachers with little or no formal preparation in issues of diversity will not be teaching in the suburban schools of middle class students. Instead, they will teach in the schools with the most vacancies—segregated rural and urban schools with large numbers of low income, diverse students.
I do not want to end this commentary by giving the impression that teacher education for diversity has not made gains over time or that the goal is too difficult and challenging to pursue. Indeed there have been many accomplishments. Over the years, multiculturalism has gained support in universities, colleges and schools of education, and society at large. We need to recognize, however, that the future of diversity in teacher education will be similar to its past. It will inevitably involve struggles for acceptance and inclusion around themes of people, pedagogy, and politics. Perhaps Marilyn Cochran-Smith (2004) is correct when she reminds us that the mere battle for social justice is, in and of itself, an acceptable measure of success.

Goodman, D. J. (2000) Motivating people from privileged groups to support social justice. Teachers College Record, 102(6), 1061–1085.
The juxtaposition of the artifacts for this section calling for dramatic change in our commitment to enhancing diversity and increasing our success with diverse students, some going back 30 years, and the calls in the three framing chapters for attention to diversity and teaching diverse learners can only infuriate anyone who sees a connection between education, democracy, and social justice. What is it about this society that allows us to satisfy our deep concerns about children who need the best education and fail to get it by simply making recommendations and not acting on them? The recommendations continue. In 2006 the College Board, in its report *Teachers and the Uncertain American Future*, makes this statement:

> We recommend abandoning the expectation that teacher-diversity goals will take care of themselves. Higher education must mount intense and targeted recruitment for minority students, programs that emphasize financial aid, along with loan forgiveness tied to years of teaching service.

(The College Board, 2006, p. 21)

The report doesn’t end there. It calls for making teaching a “preferred profession” by enhancing salaries for teachers as well as other measures, and undertaking “a national effort designed to create a teaching force that looks like America—that is to say, a teaching workforce in which the proportion of minority teachers matches the proportion of minority students” (The College Board, 2006, p. 22). In this report there also are bold recommendations about funding, and how to find the funds. But given the history of such recommendations, why should we be optimistic? We know that we continue to fail minority children. In New York City, for example, the high school graduation rate reported in 2004 was 58 percent for whites (not so great), but it was 32 percent for African Americans and 30 percent for Latinos (Orfield, 2004, p. 57). While we have not made progress, we know much more than we did when past recommendations were made. The new recommendations have the power of research to support them. This may be our last chance to make a difference. Having nearly 70 percent of minority children failing to graduate from high school in a great urban center is abysmal. Knowing that this is happening in a society that within 30 years will serve a majority of minority K-12 students is as uncomfortable a future as we can imagine. Indeed the title of Orfield’s study, “Losing our Future,” may well come to pass if we don’t act this time.

The chapter authors, all of whom are cautious in avoiding over-interpreting the research they report on, provide significant evidence that attending to diversity in teacher
education is critically important for improving the quality of education for a growing portion of our student population. Attending to diversity in teacher education means taking clear and unequivocal steps to ensure that the teaching force itself becomes more diverse to mirror the diversity of the student population and that all teachers learn how to effectively teach the diverse populations they will face in the course of their careers. It is our contention that we have failed to address this critical issue. Why have we ignored the clarion calls made ten, twenty and thirty years ago to increase the diversity of the teaching force and to improve the success rate of students of color, as discussed in the artifacts included in this section? The data presented in the three framing chapters confirm such failures and underscore the continuing challenge to all of us. We must think about what we want the future to be and how best to get there.

We could blame ourselves, and there is no doubt we have responsibility, but who are we, the teacher educators? Historically, “we” meant the faculty and administrators in schools, colleges and departments of education (SCDEs), but if we are determined to address issues of diversity appropriately, that description is not adequate. Our colleagues in arts and sciences must see themselves as teacher educators as well. In fact, most of the undergraduate students in teacher education spend the bulk of their coursework with arts and sciences faculty, not with faculty in the colleges of education. Similarly, students entering teaching at the graduate level have by and large completed full undergraduate programs in the arts and sciences without taking any education courses. Our colleagues in the public schools must identify themselves as teacher educators as well. There is compelling evidence, some of it reported in these chapters, of the critical impact that field experiences make on students’ success in becoming teachers.

If we are serious about teaching to diversity, educators in arts and sciences and in elementary and secondary schools must be substantively involved with education faculty in preparing future teachers. Students must become aware of the inequalities that exist in the U.S. among our diverse populations before they enter the professional program so they can apply these understandings in their practice. Therefore, arts and sciences faculty must develop courses that focus on issues of diversity and multiculturalism and those courses should be required as part of their general education experience. Additionally, arts and sciences faculty must encourage their students, in particular students of color, to consider teaching as a career. Too often, students enter teaching as a fall-back career, because they fail to see it valued by their arts and sciences professors. And, as all of the chapter authors propose, our colleagues in the public schools must structure field experiences for our students that are rich in opportunities to practice culturally responsive teaching. We realize that the responsibility for promoting these actions falls primarily with faculty and administrators in education who must advocate for both diversification of the teacher candidate population and assure that the professional curriculum adequately prepares them for the diversity they will encounter in their future classrooms. That part of the “we,” the teacher educators in the SCDEs, needs to make arts and sciences and public school faculty aware of the research reported here and the importance to our democracy of attending to the needs of all students. We can think of few more important actions that educators can take in the national interest than assuring that the increasingly diverse students in our schools have access to knowledge and the ability to think critically—thus closing the achievement gaps and providing them with enhanced opportunities for success in their lives.

There are examples of college, university and public school partnerships that have taken on this commitment to ensure that all these groups—faculty and administrators in education, arts and sciences, and the public schools—recognize their responsibility for preparing future teachers. Forty such settings are members of the National Network for
Educational Renewal, founded by John Goodlad. We do not mean to suggest that all of these partnerships have succeeded with this commitment or extended it adequately to addressing the diversity issues discussed in these chapters. Each of these settings, however, has an obligation to engage in research to test the assertion that when all three groups take on this challenge, we might make some headway in reducing the racial/ethnic achievement gap.

Another area for examination is the commitment to diversity embedded in the process that SCDEs seeking national accreditation must undergo. The National Council for the Accreditation of Teacher Education (NCATE), one of the two nationally recognized accrediting agencies, requires that several conditions regarding diversity be met. Standard 4, for instance, states:

The unit designs, implements, and evaluates curriculum and experiences for candidates to acquire and apply the knowledge, skills, and dispositions necessary to help all students learn. These experiences include working with diverse higher education and school faculty, diverse candidates, and diverse students in P-12 schools.

(NCATE, 2002)

The rubric used to assess the design, implementation, and evaluation of curriculum and experiences for this standard reads as follows:

The unit clearly articulates the proficiencies that candidates are expected to develop during their professional program. Curriculum and accompanying field experiences are designed to help candidates understand the importance of diversity in teaching and learning. Candidates learn to develop and teach lessons that incorporate diversity and develop a classroom and school climate that values diversity. Candidates become aware of different teaching and learning styles shaped by cultural influences and are able to adapt instruction and services appropriately for all students, including students with exceptionalities. They demonstrate dispositions that value fairness and learning by all students. Assessments of candidate proficiencies provide data on the ability to help all students learn. Candidates’ assessment data are used to provide feedback to candidates for improving their knowledge, skills and dispositions.

(NCATE, 2002, p. 29)

This is quite a complete statement of what we need—curriculum, clear statements of dispositions, knowledge, and skills, and data to provide evidence that graduates “help all students learn.” While the standard does not tell us how to go about reaching the goal, these framing chapters begin to. It should be noted that in addition to calling for a diverse cohort of future teachers who work with diverse students, the standard rightly expects a diverse faculty of teacher educators. If the standard were seriously applied, then half the teacher education programs in the nation, those accredited by NCATE, would be doing much of what the chapters in this section call for. It would be productive to determine whether differences exist in the extent to which graduates of NCATE accredited institutions that meet and do not meet the diversity standard (which would not disqualify them necessarily for accreditation) succeed in teaching students of racial/ethnic backgrounds.

Another aspect of teacher education that is part of the current landscape, and addressed in this section of the Handbook, is the appropriateness of assessing and developing dispositions during the admissions process and throughout the program. Increasingly, commentators writing in major news magazines and newspapers are challenging the use of dispositions for assessing teacher candidates. Their argument is that developing
dispositions in candidates is a form of “mind control” and “left-leaning politics” when dispositions hint of elements of social justice. We believe instinctively, and with some evidence, that dispositions—which we view as comprised of attitudes, values, beliefs and actions—are important, particularly in preparing teachers to work effectively with students of cultural backgrounds different than their own. The dispositions often mentioned include respect for others who come from diverse backgrounds, belief in the importance of multiculturalism to a democracy, and empathy for those not treated equitably in society because of their difference. These dispositions are very complex sets of attributes and behaviors, and programs should use them as one factor in assessing students. We believe, for example, that if a teacher education student does not have a firm conviction that all children should have equal learning opportunities, there is likely insufficient time in the professional sequence of courses to change such a disposition. Additional research is needed to probe the links between teacher dispositions towards diversity and student learning.

Concern for the values and beliefs of teachers and their students on important issues related to cultural differences is not a new concept in teacher education. More than 30 years ago the American Association of Colleges for Teacher Education’s issued its “No One Model American” statement which called for the teaching of values that support cultural diversity and individual uniqueness (AACTE, 1973). That document called for teaching such values at every level, including within programs for teacher education. Opposition to such long-standing positions are not based on new evidence—in fact as we see in these chapters we have, if anything, more of a basis for concern about such values and belief. Clearly the opposition has a basis in political dogma and ideology, which will unfortunately make further change in support of this work even more difficult.

The concern about dispositions raises another issue important to this discussion. Many critics of the work described in these chapters believe that the purposes of public education are narrowly constrained to clearly measurable knowledge and skills. Certainly the basis for adequate yearly progress that is part of No Child Left Behind would suggest that achievement on standardized tests is the single most important variable in judging a school. A very telling statement that illustrates this narrow position, especially in the context of multicultural education, comes from Chester Finn, President of the Fordham Foundation, who wrote:

Civic education may sound like a good idea in theory, but in practice public schools could even do harm in this realm. Some educators harbor worrisome values: moral relativism, atheism, doubts about the superiority of democracy, undue deference to the “pluribus” at the expense of the “unum,” discomfort with patriotism, cynicism toward established cultural conventions and civic institutions. Transmitting those values to children will gradually erode the foundations of a free society. Perhaps society would be better off if its schools stuck to the three R’s and did a solid job in domains where they enjoy both competence and wide public support.

(Finn, 2004, p. 14)

The research and recommendations reported in this section indicated the need for increased deference to the “pluribus” rather than the “unum.” We can only reach the goal of “one out of many” when we attend to the needs of the many and equip them for full participation in society. Furthermore, a focus on “the three R’s” is too narrow a definition of what we should expect of education in a democracy. We argue that we need educators who understand the full scope of the following four enduring purposes for public education:
preparing each new generation to live in a socially just democratic society;
providing access to knowledge and critical thinking for all students;
helping students imagine and achieve all the possibilities for their place in society,
and to have full access to life’s chances; and
enabling students to lead rich and rewarding personal lives characterized by understanding all aspects of human knowledge, including aesthetics, creativity, and personal health.

(Michelli, 2005)

What about the claim that No Child Left Behind, by requiring the disaggregated reporting of student achievement scores, will shine the light on inadequacies and foster reform? Several states, including New York, have reported disaggregated data for some time, and that alone has not led to reform. In fact, despite a court order mandating redistribution of educational resources to those cities in New York with the largest populations of students of color, the governor and legislature have yet to act on the order. But the kind of data NCLB yields may help in some jurisdictions. One affluent Virginia district recently “discovered” that African American students in the district were doing less well than students in large cities in Virginia, including Richmond and Norfolk. The superintendent said, “We had a perception that our performance is higher than the data would indicate, in part because of the accolades our schools get. Until you peel back the onion a little bit, you may not see areas where you are not successful” (The Washington Post, April 14, 2006, p. A01). So this is important information for the district, and it is of course surprising that they didn’t know already. How will the district react? Time will tell, but what has happened elsewhere is that instead of focusing on the ability of teachers to successfully teach students of color, there has been a narrowing of the curriculum and an increased focus on what gets measured (Center of Education Policy, 2006). Not all of the purposes of education are served by this focus on standardized test scores. We cannot assume that even by exposing disparities like the one in Virginia the solution will be in keeping with all the recommendations of the chapters in this section.

There is still another factor that explains this failure to adequately prepare future teachers to ensure the success of all students, one that has already been alluded to in this commentary, and perhaps the most difficult one to overcome: the lack of political will to address the issues. Where are the policymakers in this? Where in policy do we find evidence that they have acted to assure that teacher education programs are designed to prepare teachers who can meet the standards we aspire to? Where are the resources to support excellent education and professional development in high need districts? Where is policy that requires public schools and arts and sciences departments to participate in teacher preparation? They are largely absent and we need to find out why. What drives policy makers? What prevents them from taking the actions we think they should take? Is it our failure to adequately educate them or the populace that elected them? Or is the problem rooted in ideological differences that are impossible to reconcile? George Lakoff’s (2002) concept of “world view” may be applicable here. Is it possible that politicians and educators hold different world views—that is, different attitudes, values, beliefs about, and goals for, public education—that preclude a meeting of the minds?

Several principles of practice related to preparing teachers to teach diverse populations emerge from our experiences. We suggest that each can be the basis for research. First, those preparing teachers and other public school educators must have a clear, unambiguous shared vision that addresses the four enduring purposes of public education listed above. The vision must be the basis for all important academic decisions. A shared vision, as Peter Senge (1993) has suggested, is very powerful. When there is a shared vision, all
participants understand with clarity what the goals are and what must be done to achieve them. A part of that shared vision must focus squarely on issues of diversity and meeting the needs of all students in schools. We cannot, for example, hide behind a program standard, including an accreditation one, without being clear about what it means to really meet it. Decisions about admission, curriculum, assessment, research agendas, and resource distribution, to name a few, must flow from the vision. A professional program needs a shared vision to make it effective, coherent, and distinctive. Developing such a vision requires a great deal of collaboration and professional development of all involved in educating educators and P-12 students. It is only through common readings, in-depth discussions, and a focused research agenda that we reach a shared vision. This is especially true in an area as complex as dealing with diversity in these times.

Second, teacher preparation programs and programs in public elementary and secondary schools must be renewed simultaneously. We cannot achieve our goals for diversity from either the vantage point of higher education or from the P-12 schools alone. It makes no sense to prepare teachers with the knowledge, skills and dispositions they need to be successful with all students if the system they work in does not embrace these goals overtly and consciously work towards them. We need to develop our research and educational agendas together, not separately.

Third, faculty and administrators in education, the arts and sciences, and the public schools must work together as equal partners in the preparation of future educators and in the renewal of education. To successfully diversify our faculties and reach all children, all must share both authority and accountability. Formal structures to support this collaboration and appropriate reward systems need to be developed. A failure to include all who must be involved inevitably leads to finger pointing. We are all in this together! Admittedly, this is an incomplete list of who must be involved. By mentioning faculty and administrators we mention only those directly involved in this work on a daily basis. We cannot forget the importance of collaboration with policy makers, parents, business and community leaders.

Fourth, teacher educators must collectively advocate for teaching for democracy and social justice to ensure equity for all children. The authors of these chapters have set goals that are not only educational, but political and moral as well. Teacher educators must be grounded in all of these perspectives in order to successfully advocate for programs that meet the needs of all students, especially those from high need areas. Unless we are active in doing this, we have not fulfilled our professional responsibilities.

Lastly, excellent programs assess their outcomes regularly, and provide evidence relating to the full range of their vision for public schools and the education of educators. We must be willing to assemble the evidence about what works in achieving our goals. This is an important, but daunting task. Even when we focus on what one would expect to be the most easily measured outcome of schools—student knowledge—the task is complex. A research project underway in New York City is described in an article appropriately entitled Complex by Design (Boyd et al., 2006). In that study, researchers seek to determine the effectiveness of the many pathways into teaching in New York City using a variety of measures, including value added assessment (where adequate data are present). This research needs to be extended to determine the success of teachers who complete different programs with a variety of school populations that differ in race, culture and language. This is a measure of only one of the outcomes we hope for in education, and each college and university must use qualitative and quantitative measures where appropriate to examine their impact on the full range of sought after outcomes.

Programs also need to assess themselves with respect to factors that affect their ability to prepare teachers of color by examining barriers to program completion. The work at
the University of Illinois at Chicago is an excellent example of a program that found factors working against African American students’ success and made programmatic changes that eliminated the barriers (see Chou et al., 2006). Similarly, work at Boston College (see Cochran-Smith et al., 2006) and at Montclair State University (see Villegas & Lucas, 2006) that aims to assess achievement of difficult to measure outcomes related to social justice and diversity represent promising lines of research and development.

What can we conclude? The authors of the framing chapters in the diversity section of the Handbook have added to our knowledge base and we clearly know more than ever before about the connections among diversity, student learning, and a commitment to social justice. There is more to be done to test our assertions and common convictions. We need evidence of what works across the broad spectrum of the purposes of education in a democracy and the political will to make a difference. We need to examine ourselves, perhaps even redefine who we are and how we hold ourselves accountable. The changing demographics of the next several decades require that we take action through research and practice to assure that all children reach their fullest potential in life.

37 Troubling diversity

Victoria Chou and Karen Sakash
University of Illinois at Chicago

The construct “diversity” is vague enough that it can mean almost anything to anyone. It is both inoffensive and plastic, so it can fit very different ideological and educational orientations. And when no rationale for privileging one kind of diversity over another is readily available, all are equally valid or easily trivialized. It is safe to say that virtually every teacher education program in the nation claims to teach for diversity, despite the evidence that our graduates are not serving the educational needs of all groups equitably.

This section of the Handbook offers a clear focus on how diversity operates in three distinctive sectors of teacher education: the preparation of White teachers to teach students of diverse backgrounds (Sleeter), the recruitment and preparation of teachers of color (Villegas and Davis), and the preparation of all teachers—regardless of their backgrounds—to teach English language learners (Lucas and Grinberg). Our essay builds on the discussions of these three aspects of teacher education, as developed in the framing chapters, and raises additional questions about how race and language are or ought to be addressed in the education of teachers today. By way of conclusion, we discuss how schools of education must “trouble diversity,” to borrow Kevin Kumashiro’s (2002) language of complicating existing paradigms, to create a truly pluralistic approach to teacher preparation.

ON PREPARING WHITE PRESERVICE TEACHERS TO TEACH STUDENTS OF DIVERSE BACKGROUNDS

Sleeter’s platform for preparing White preservice teachers to teach students of diverse backgrounds rests on three supports: (1) cross-cultural community-based learning, (2) professional coursework on culture and equity pedagogy, and (3) field experiences in classrooms that serve students of color.

We emphatically agree with Sleeter that White teacher candidates need community-based learning experiences to build an experiential foundation for teaching students from cultures other than their own. We have learned that this cannot be accomplished on the fly during student teaching, however. Finding time, curricular space, and adequate funding for these experiences is challenging. There may be insufficient time in the typical teacher preparation program for the necessary cultural learning to go beyond eye-opening. Can a semester- or even a year-long experience effect deep attitudinal change? Or should we select into teacher education only those applicants who already possess dispositions that are supportive of diversity? Cross-cultural community-based learning is insufficient to prepare White preservice candidates to teach “other people’s children” well, unless they are already favorably inclined toward diversity from the start of the program.
Like Sleeter, we believe that cross-cultural community-based learning experiences must be “well-planned, linked directly to teacher education, and involve guided reflection.” We recognize, however, that the vast majority of teacher educators themselves have received little or no preparation to support preservice candidates in these experiences. Without understanding how our own dysconscious racism, to use Joyce King’s (1990) phrase, operates in schools and communities, we (teacher educators) may unwittingly perpetuate stereotypes by positioning our teacher candidates as naive voyeurs who barge carelessly into community places and make uninformed critical judgments about what they are seeing.

We also endorse Sleeter’s recommendation for professional coursework on culture and equity pedagogy. Such coursework can map a progression from big-picture analyses of culture and institutional racism—such as those posed in the Glazer (1993) artifact—to self-examination, to pedagogical applications for the classroom. In our particular institutional context, our biggest challenge lies in getting teacher education faculty to make the shared programmatic commitment that results in a coherent curriculum organized around culture and equity pedagogy. Albeit challenging, it is critical for teacher educators to make the shared programmatic commitment that results in a coherent curriculum organized around culture and equity pedagogy. Despite our own university’s avowed commitment to serving its urban community, we know that the problems of institutional racism pervade all of the nation’s schools in urban, suburban and rural locales, our own included. As such, the University of Illinois at Chicago (UIC) is a land-grant institution with an avowed commitment to serving the urban context. We recognize that most institutions do not have such an explicitly urban mission. We know, however, that the problems of institutional racism pervade the nation’s schools in urban, suburban, and rural locales. As such, every teacher education program needs to place at the center of its work the preparation of teachers to counter the effects of that racism.

The segregated disciplinary spaces within schools and colleges of education make it difficult for us to act as a holistic and reflective learning community. While exceptions exist, faculty taking an explicitly “critical” theoretical orientation often reside in social foundations departments. Methods faculty, in the typical division of program labors, are often focused on more disciplinary concerns, while faculty who supervise student teachers are generally more interested in basic pedagogical development. Faculty responsibilities are frequently divided between teacher preparation and advanced graduate programs related to specialized disciplinary and research interests, with the infelicitous outcome that many faculty view their teacher education work as little more than “service” contributions which are not central to their research agendas. Add to this a general education curriculum that usually resides outside the school/college of education and must respond to the always-changing State curriculum mandates. Given these divergent interests and perspectives, the development of a coherent curriculum that can equip candidates to challenge the status quo presents a seemingly insurmountable challenge.

How to secure teacher educator buy-in to create a coherent curriculum that focuses on culture and equity pedagogy is a major challenge to us all. We are well aware of the problematic nature of approaching this task by “going with the goers” (Au, 2005). Such an approach tends to divide the faculty, build resistance among those who elect not to go, and lower trust all around. We need to think seriously about the kinds of conversations and professional development needed to foster common understandings about the desired curriculum. We also need to explore the kinds of institutional incentives that must be in place to make this happen.
We have dedicated considerable efforts and resources to developing field experiences in classrooms that serve students of color, the third leg of Sleeter’s platform. As such, we are acutely familiar with the challenges of developing excellent field experiences in schools in economically oppressed communities. We realize that many teacher educators are disinclined to place teacher candidates in classrooms where practicing teachers are perceived to engage largely in didactic, scripted teaching and test preparation—strategies that sadly abound in urban schools. In these settings, the collaborative resonance approach proposed by Cochran-Smith (2004), which calls for teacher candidates to work with practicing teachers to connect critique with practice, would be most appropriate. We submit the following cautions, however. The data on the effects of didactic, scripted teaching on student learning are decidedly mixed, as are the data on more inquiry-based teaching approaches. Moreover, schools in historically oppressed communities, many of which fall under NCLB sanctions, are not offered the curricular and instructional freedoms afforded other schools. It is also important to remember that White, “progressive” teacher educators’ perspectives on what is good teaching often differ from the perspectives of good teaching held by members of racial/ethnic minority groups. So long as members of the teaching profession are predominantly White, the language and programmatic emphasis of social justice are likely to prevail over programmatic emphases that enable African American and Latino teachers to teach the children and youth of their own communities of color.

So long as members of the teaching profession are predominantly white and middle-class, we need to stay alert to the fact that their programmatic preferences and emphases may be unjustifiably privileged over those of African American and Latino teachers who are teaching the children and youth of their own communities of color. When we attempt to place teacher candidates in exclusively Black schools, however, at least some teacher candidates and faculty employ “diversity” in a rationale of resistance, i.e. claiming that schools with a homogeneous Black student body are not sufficiently diverse. This is especially problematic in school districts like Chicago in which 46 percent of all schools have student enrollments that are at least 90 percent African American. As teacher educators, we must confront and address our own and teacher candidates’ discomforts and fears about working with “others.”

ON RECRUITING AND PREPARING TEACHERS OF COLOR FOR STUDENTS OF COLOR

We could not agree more with the arguments of Villegas and Davis for increasing the recruitment of people of color into the teaching profession. Their “leaky pipeline” metaphor describes the terrible loss of students of color at every point along the educational continuum. Consequences of such losses echo the devastating impact of the dismissal of more than 38,000 Black educators in the decade following the 1954 Brown v. Board of Education of Topeka decision, as Ethridge (1979) aptly points out. A disproportionate number of the overwhelmingly Black and Latino graduates of urban public school systems nationwide who enter college do so with academic gaps that must be addressed before they can be admitted to teacher preparation programs. Rather than merely serving as gatekeepers, it behooves us in schools and colleges of education to join our arts and sciences colleagues to help address the learning gaps among students of color at our institutions. Once students of color are in our programs, we must remain vigilant to ensure they are well supported through graduation and beyond in their teaching careers.
Otherwise, the cycle of negative consequences for students of color in this country will never be broken.

Villegas and Davis argue that teacher preparation programs concentrate almost exclusively on the needs of White teacher candidates, overlooking the needs of prospective teachers of color. We find historical resonance in Glazer’s (1993) account of the way in which the concept of assimilation never embraced African Americans. Like Villegas and Davis, we think it is of paramount importance for teacher educators to devote significantly more attention to the needs of preservice candidates of color. In our view, the needs of this group cannot be adequately addressed without a critical mass of teacher educators of color. The American Association of Colleges of Teacher Education’s “Multicultural Statement No One Model American” recognized this in 1972. Evidently, it is harder to apply the lesson than to make a statement. And just as teacher educators must create a safe environment for dialogue among teacher candidates, so too must teacher educators of color be assured of a safe environment for dialogue among their colleagues. Faculty members of color bring distinctive perspectives that enrich the content and conduct of teacher preparation programs. While their numbers are increasing, many more are needed.

While prospective teachers of color enter their preparation programs with cultural knowledge and experiences that place them at an advantage over their White counterparts in teaching students of color, Villegas and Davis affirm that they nevertheless also need support translating such knowledge and experience into sound pedagogical practices. If we take seriously Gloria Ladson-Billings’ (1995) assertion about inserting education into the culture, rather than vice versa—and at UIC we do—then we have to consider the cultural backgrounds of our teacher candidates just as we ask them to consider the cultural backgrounds of their future students. Given that most teacher preparation programs draw at least some students from non-mainstream backgrounds, we ourselves need to engage in differentiated instruction to prepare future teachers, regardless of their race/ethnicity, to teach racially and ethnically diverse student populations. That is, we need to model what we teach.

ON PREPARING ALL TEACHERS TO TEACH ENGLISH LANGUAGE LEARNERS (ELLs)

Lucas and Grinberg explain why, in recent years, greater numbers of English language learners have been taught in mainstream classrooms by teachers who have received no special preparation for undertaking this task. As these authors point out, content related to teaching English language learners too often is absent from the curricula of teacher preparation programs in early childhood, elementary, and secondary education. If second language learning issues are addressed, they either are melded into an unwieldy multicultural course or loosely bundled with other multicultural content into the overall teacher preparation curriculum. In the former case, teacher candidates have no access to key language-related topics; in the latter case, those issues are submerged in a host of competing “diversity” topics. And in neither case are classroom teachers provided with direct experience working with English language learners. Fortunately, in recent years, federal funding focusing on programs that target “all” teachers has enabled more teacher candidates to take coursework leading to ESL endorsements and credentials. Such efforts have the potential for breaking down some of the attitudinal barriers pointed out by Lucas and Grinberg.
There are other ways that teacher education programs can prepare prospective mainstream classroom teachers to teach ELLs. For example, placing non-bilingual teacher candidates to learn side-by-side with bilingual teacher candidates could help both groups naturally develop new understandings related to language and culture. Non-specialists could also be placed in bilingual/ESL classrooms for at least a portion of their field experiences. And pairing bilingual and non-bilingual teacher candidates in field experiences can facilitate richer conversations about appropriate instruction for ELL students.

We see these pairings between bilingual and non-bilingual teacher candidates mirrored in the increasing collaborations between regular classroom and bilingual/ESL teachers (Mosca, 2006). We know that greater communication between these two groups at the preservice level can be key to promoting knowledge-sharing in their future work as teachers in schools. Both sets of teachers benefit from collaborative relationships, and when the students are mixed for instruction, everyone learns more about language and culture (Whitmore & Crowell, 2006).

Another trend that parallels teacher collaboration is the increase in dual language programs which are implemented using many different models, but often result in a whole-school focus on valuing two languages for instruction (Cloud et al., 2000). Often, teachers proficient only in English become involved in the English instructional component in dual language instruction. We are also seeing increased attention to professional development to prepare regular teachers to support English language learners through content-based ESL instruction (Echevarria et al., 2000). More regular classroom math, science, social studies, and other content-specific teachers have come to understand their role in making their lessons comprehensible for English language learners. We believe teacher candidates would benefit from experiencing the variety of learning environments available to English language learners.

Similar to the argument made above for teacher educators of color, if more bilingual/ESL faculty were hired into general teacher education positions, the knowledge base regarding English language learners would grow. Whether or not a teacher educator is bilingual may matter less than the individual’s informed understanding of current assessment and instruction policies at the local, state, and national levels. All teacher educators need to know the current policies regarding the education of English language learners. The recruitment of more bilingual individuals into the teaching profession continues to be important, and more so now that federal and state policies are de-emphasizing native language instruction and fewer federal scholarship opportunities for preparing bilingual teachers are available. Perhaps teacher accreditation bodies such as the National Council for the Accreditation of Teacher Education (NCATE) can grapple with the “Call to Action” outlined by AACTE’s Committee on Multicultural Education (2002) to shed light on the specific teacher preparation work needed to advance the field beyond a surface understanding of the concept of “diversity” and recognize the urgency of providing the best education possible for English language learners and those who educate them. But teacher education programs need not wait for NCATE to act on this matter.

IN CLOSING

Our essay suggests how schools of education might “trouble diversity.” In our combined 56 years of higher education experience, developing an effective approach to culturally pluralistic teacher preparation is the hardest job we have ever tackled. Traditional teacher preparation for a predominantly White teacher force—most often grounded in
mainstream values and principles—make it much easier to go with the cultural and linguistic assimilation flow. Breaking with this tradition involves helping teacher candidates ground their teaching in the culture and language of the students they teach. This requires that future teachers develop a deep understanding of the ways of knowing, learning, and behaving of others who are different from themselves. Equally important, they must learn to see themselves in relation to those others. Accomplishing this is no easy task.

It is time to take a critical, reflexive look at how poorly we are serving the learning needs of millions of African American and Latino students who continue to be left behind. We must move beyond so-called diversity standards to familiarize ourselves and our teacher candidates with the cultural particulars of the students we serve and the concomitant implications for teaching and teacher preparation.

INTRODUCTION

A recent publication sponsored by the National Academy of Education carries the title, “Preparing teachers for a changing world: What teachers should learn and be able to do” (Darling-Hammond and Bransford, 2005). The formulation of the sub-title with its explicit use of the verb “learn” reflects a subtle but important shift in how researchers are beginning to think about and study the professional education and development of teachers. The more common and related question, What do teachers need to know, care about, and be able to do, has preoccupied teacher educators and scholars of teacher education for over a century and continues to do so. At the same time, researchers have come to appreciate that learning to teach extends beyond the boundaries of formal teacher education. Moreover, questions about the content of teacher learning are not the same as questions about how teachers acquire, generate and learn to use knowledge in teaching. Influenced by developments in learning theory and new understandings of teaching, scholars are shaping a new area of research on teacher learning with important implications for teacher education policy and practice.

A messy problem space

When we talk about research on teacher learning, we generally mean research on how people learn to teach and develop their practice over time. But this seemingly straightforward statement embraces conceptual and empirical questions about the content, processes, opportunities and contexts of teacher learning. It also implies questions about the consequences of teacher learning. What do teachers need to learn in order to help all students achieve their potential? What kinds of intentional learning opportunities help teachers acquire and develop the vision, knowledge, practices, frameworks and dispositions they need to promote student learning? Since becoming an accomplished teacher happens over time across settings, research on teacher learning includes studies of what teachers learn from teacher preparation and professional development and how they use what they learn in teaching. It also includes studies of what teachers learn from the daily experiment of teaching and from informal interactions with colleagues. Ultimately research on teacher learning must consider how the outcomes of teacher learning contribute to student learning. How else will we know whether teachers’ newly acquired knowledge and skills are helping them become more effective teachers?

Research on teacher learning involves value-based considerations as well. The knowledge, skills and commitments that teachers need to learn derive from a conception of accomplished teaching which in turn reflects a view of what students should learn and what schools are for. The connection between public expectations for schooling and
requirements for teacher learning is expressed in prescriptions for the curriculum of
teacher education, in professional teaching standards, and even in expectations for
research on teacher learning. For example, the rationale for linking evidence of teacher
learning with evidence of student learning comes in part from the educational imperative
to enhance learning outcomes for a diverse student population.

Research on teacher learning is a complex area of inquiry that sits at the intersection of
several fields of research and areas of study, including research and theories of learning,
studies of teaching and teacher knowledge, research on teacher preparation, new teacher
induction and professional development, studies of school change and teaching culture.
This explains the inevitable overlap between the contents of this section and other sec-
tions in this Handbook, especially “Teacher Capacities: Knowledge, Beliefs, Skills and
Commitments,” and “Diversity and Teacher Education.” It also underscores the challenge
of designing the kind of research that considers the interaction of person, program and
school setting; accounts for changes in what teachers know, do, think and feel over time;
and addresses the question of how teacher learning promotes student learning.

The diverse intellectual roots of research on teacher learning, the need to connect
different lines of work, the mix of descriptive and normative issues, and the variety of
frameworks and paradigms that researchers have used to study teacher learning compli-
cate the task of synthesizing what we know and what we need to learn. Still, we have
made some progress in conceptualizing and studying what learning to teach entails since
the 1980s when teacher learning emerged as a new focus of research (Cochran-Smith and
Fries, this volume).

A thematic framework of learning to teach

Learning to teach can be conceptualized around four broad themes—learning to think
like a teacher, learning to know like a teacher, learning to feel like a teacher and learning
to act like a teacher. This formulation highlights major theories and findings in research
on teacher learning. Compatible with contemporary frameworks for understanding
teaching and learning, it underscores the interconnections of content, process and contexts
in learning to teach.

The first theme—learning to think like a teacher—points to the intellectual work of
teaching and the influence of cognitive science on studies of teacher learning. Learning
to think like a teacher requires a critical examination of one’s existing beliefs, a transition
to pedagogical thinking, and the development of meta-cognitive awareness. A substantial
body of research documents the beliefs that teachers hold and the ways in which these
beliefs influence what teachers do and do not learn from professional education and
teaching. (For reviews, see Richardson and Placier, 2001; Wideen et al., 1998). Without
an opportunity to examine critically their existing beliefs in light of new possibilities and
understandings, teachers may ignore or distort new ideas and practices.

Learning to think like a teacher means moving beyond naïve beliefs, for example, that
teaching is easy and learning involves the simple transfer of information from teacher
to student, to embrace more defensible views of teaching, learning, subject matter and
students. It means learning to place the activities of teaching and learning in a pedagogical
framework that links ends and means (Lortie, 1975; Feiman-Nemser & Buchmann,
1986). It means developing the capacity to think on one’s feet, reflect on and adjust one’s
practice.

The second theme—learning to know like a teacher—highlights the different kinds of
knowledge that good teaching depends on, including the knowledge teachers generate in
practice. (For a discussion of views of knowledge and their implications for teacher
learning, see Cochran-Smith & Lytle, 1999.) Teachers need to know a great deal in order to enhance the academic learning of all students. They need deep knowledge of subject matter and how to teach it to diverse learners (Ball & McDiarmid, 1990; Kennedy, 1991). They need to understand how children grow and learn and how culture and language influence their learning. They need to know about curriculum, pedagogy, classroom organization and assessment. They need to understand the broad purposes of schooling and how those purposes affect their work. (For a recent synthesis of knowledge for teaching, see Darling-Hammond & Bransford, 2005.)

Depth and breadth are two important dimensions of teacher knowledge. Equally important is how teachers organize and “hold” their knowledge. Considerable research on learning indicates that competence in a given area depends on having a solid foundation of factual knowledge organized around a conceptual framework and held in ways that facilitate retrieval and use (National Research Council, 2000). This principle has important implications for the curriculum of teacher education and professional development, and for our understanding of teaching and teacher learning.

Besides knowledge for teaching which can be learned outside practice, teachers need knowledge of teaching which can only be gained in the context of their work. For example, teachers may anticipate what students will find difficult or confusing, but they cannot know ahead of time how particular students will make sense of what they are learning. This underscores the importance of learning to learn in and from teaching.

The third theme—learning to feel like a teacher—signals the fact that teaching and learning to teach are deeply personal work, engaging teachers’ emotions and identity as well as their intellect. Forming a professional identity is a complex process that fuses past, present and future ideals and realities (Featherstone, 1993). What kind of self-knowledge do teachers need, especially when they teach students whose backgrounds differ from their own? How do teachers manage the gap between their vision of the kind of teacher they want to be and the realities and challenges they face (Hammerness, 2006; Ladson-Billings, 2001)? How do teachers reconcile different images of themselves as teachers and colleagues and develop an earned sense of intellectual and moral authority (Roosevelt, 2007)?

For some time, discussions of teacher capacity have been framed in terms of knowledge, skills and dispositions. Dispositions unite ability with desire, orienting teachers to act in particular ways (Schwab, 1976). For example, the disposition to see all children as capable of learning leads teachers to hold high standards, to seek out students’ strengths and interests as a foundation for learning, and to persist in helping all students find success. Accomplishing these goals may require collaboration with colleagues’ more than heroic efforts on the part of individual teachers. McDiarmid and Clevenger-Bright (this volume) criticize prevailing views of teacher capacity as “too static and individualistic” and argue that teachers need the dispositions to participate productively in communities of practice and to examine their teaching in light of a range of evidence.

Ultimately teachers must learn to integrate ways of thinking, knowing, feeling and acting into a principled and responsive teaching practice. Inside the classroom, teachers engage in a wide range of activities—explaining, listening, questioning, managing, demonstrating, assessing, inspiring. Outside the classroom, teachers must plan for teaching, collaborate with colleagues, work with parents and administrators. The complex, uncertain, multidimensional nature of teaching exacerbates what Mary Kennedy (1999) calls the “problem of enactment”—putting one’s intentions into action.

To act like a teacher, teachers need a repertoire of skills, strategies and routines and the judgment to figure out what to do when. The normal busyness of classrooms requires the establishment of routines to make teaching manageable. At the same time, the
unpredictability of teaching means that teachers are constantly absorbing new information and using it to decide what to do next. So learning to act like a teacher means developing what cognitive scientists call “adaptive expertise” (Hatano & Oura, 2003).

**Cognitive science and teacher learning**

New understandings from cognitive science about how people learn are beginning to influence our understanding of how teachers learn to teach and develop their practice over time. In a review of research on learning to teach, Borko and Putman (1996) offer a succinct definition of learning from a cognitive science perspective. Learning is “an active, constructive process that is heavily influenced by an individual’s existing knowledge and beliefs and is situated in particular contexts” (pp. 674–675). This definition highlights two key ideas. Learning is not a passive process of absorbing new information. Like all learners, teachers interpret new knowledge and experience through their existing beliefs and modify and reinterpret new ideas on the basis of what they already know and believe. What teachers learn is also influenced by the social and cultural contexts where knowledge is acquired and used, including the particulars of subject matter and students.

Many early studies of teacher learning focused on individual teachers and the changes that did or did not occur in their knowledge and beliefs as they participated in teacher education and professional development. More recently, researchers have adopted broader perspectives that consider the interactions between what teachers bring and what they encounter, including the contexts of their learning. Socio-cultural theories are particularly useful in longitudinal studies of learning to teach because they focus on how the various settings in which teachers learn—university courses, student teaching, schools and classrooms, mentoring relationships—enable and constrain their adoption and use of new knowledge and practices and their ongoing learning.

In one study, for example, researchers (Grossman et al., 1999) followed a group of beginning elementary and secondary teachers from their last year of teacher education through their first three years of teaching. They found that the teachers used the reflective stance they had developed during their teacher education program to make sense of their teaching situation. Although some struggled as first year teachers, by the second year, most were able to use specific pedagogical tools (e.g. Writers Workshop) they had learned about in teacher education. The research team also identified particular aspects of the school and district context, including access to particular curricular materials and professional development opportunities, which dramatically affected teachers’ on-the-job learning and their ability to use ideas and strategies introduced in teacher education. Some of these ideas and perspectives are taken up in the framing chapters and artifacts which make up this section.

**The framing chapters**

Each of the three framing chapters deals with an enduring aspect of teacher learning. Cheryl Rosaen and Susan Florio-Ruane examine the necessary but problematic role of experience in learning to teach. Carol Rodgers and Katherine Scott focus on the process of identity formation in teachers. Joel Westheimer considers colleagues as a salient resource and context for teacher learning. These chapters examine familiar issues in new ways and introduce emerging areas of scholarship on teacher learning.

While no one denies the essential role of experience in learning to teach, we may not appreciate the role that language plays in mediating what teachers can and do learn from first hand experience. In “The Metaphors By Which We Teach: Experience, Metaphor
and Culture in Teacher Education,” Rosaen and Florio-Ruane look at the experience of teaching and learning to teach through a socio-cultural lens, asking what and how prospective teachers learn in terms of their work and identity. They argue that experience is not only an essential activity by means of which a beginner learns to teach and is inducted into a practice and community of practitioners, it is fundamentally shaped by pervasive metaphors in our culture. To illustrate their argument that metaphors influence what teachers learn from university and school-based experiences, the authors examine the meanings and potential impact of three common metaphors—field experience, struggling reader and at risk learners. One implication is that novices may have difficulty learning well from experience without professional education that equips them with frameworks to interpret and organize their insights about students and to sort out the implications for teaching.

In “The Development of the Personal Self and Professional Identity in Learning to Teach,” Carol Rodgers and Katherine Sullivan open up an important aspect of teacher learning that has not been the subject of much empirical investigation. Teachers construct a sense of themselves as professionals by combining parts of their past and pieces of their present with images of the kind of teacher and colleague they want to become and the kind of classroom they want to have (Featherstone, 1993). The identities teachers form influence where they put their effort and guide them in carrying out their responsibilities (Hammerness, 2006). But teacher identity is not fixed and unchanging. Reviewing contemporary conceptions of identity, Rodgers and Sullivan point out that teacher identity is shifting, multi-faceted, formed in relationships, influenced by contexts, constructed in stories. Rodgers and Sullivan are especially interested in how teachers can learn to “author” their own professional identity. They introduce Robert Kegan’s constructivist-developmental theory as one framework for thinking about the psychological circumstances under which this is more or less possible. They also provide examples of historical and contemporary teacher education programs that take identity formation seriously and suggest needed research, including attention to issues of race, class and gender in teacher identity formation.

Two decades of research on teacher community and teacher collaboration have produced compelling evidence that improvements in teaching are most likely to occur in schools where teachers work together. Whether the focus is on novices learning to teach in the company of mentors or teachers at different career stages coming together to develop curriculum, analyze student work, discuss problems of practice or implement a new instructional program, researchers are demonstrating the power (some would say necessity) of collective activity to strengthen teaching and enhance student learning. Joel Westheimer reviews much of this research in his chapter, “Learning Among Colleagues: Teacher Community and the Enterprise of Education.” The chapter is organized around five goals that researchers and reformers have set for professional learning communities among teachers. Westheimer also discusses challenges to teacher learning in community such as teacher isolation, the constraints of time and space, and the tension between inclusivity and competing ideologies. Finally he shows how the community metaphor intersects with notions of democracy, social justice, and visions of the good society.

The artifacts

The three artifacts that accompany this section span the twentieth century, illustrating the persistence of concerns about teacher learning. Although empirical studies of teacher learning did not emerge until the 1980s, the idea of teachers as learners was articulated decades earlier by progressive educators like John Dewey and Lucy Sprague Mitchel.
whose views of learning are compatible with contemporary socio-cultural theories. The Dewey essay examines the proper focus of teacher preparation in laying a foundation for continued learning from teaching. The Mitchel chapter outlines a large-scale experiment in inservice education that transformed urban teachers’ practice and identity. Berliner’s essay on the development of expertise in teaching lends empirical support to the fact that learning to teach well happens over time and does not automatically result from teaching experience. Read as a set, the artifacts offer different answers to the question of how teacher preparation and professional development can assist teachers along the path toward adaptive expertise.

In his 1904 essay on “The Relation of Theory to Practice in Education,” Dewey distinguishes two approaches to practice work in teacher education, the laboratory approach and the apprenticeship. Influenced by the rise of the research university, Dewey favored the laboratory approach. In his view, teacher preparation should develop the intellectual habits needed for personal mastery of practical skills rather than focusing on developing technical proficiency “lest immediate skill be got at the cost of the power to go on growing.” For Dewey, the supreme mark of the teacher is the ability to interpret and activate students’ motivational and intellectual processes. To do this, teachers need the capacity to see what is going on in the minds of their students and to figure out how to engage them in worthwhile learning. If student teachers are faced with the challenge of managing a class before they become students of subject matter and learning, they will develop their teaching habits on the basis of “what works” to maintain order rather than what pupils need to move their learning forward.

It is easy to misread Dewey as making the case for studying theory before encountering practice. Actually the sequence he outlines involves the study of subject matter and educational psychology in conjunction with critical reflection on personal learning experiences, focused classroom observations, tutoring, curriculum investigation and curriculum development as foundations for more practical experience. Although his language may be quaint, Dewey’s recommendations for inquiry-oriented, content-rich, learning-centered teacher preparation foreshadow contemporary teacher education programs committed to laying a foundation for learning in and from teaching (see Darling-Hammond, 2000).

The second artifact from Our Children, Our Schools by Lucy Sprague Mitchel, founder of Bank Street College, describes a system-wide inservice experiment in the 1940s which introduced progressive educational ideas and practices to teachers in the New York City public schools. The chapter, “Growth of Teachers in Professional Maturity,” documents the stages teachers went through as they unlearned traditional attitudes and pedagogies, constructed a new professional identity, and learned new ways of working with children and content.

In the beginning, teachers were impatient with talk by the Bank Street Workshop staff about what children are like or how to fit a curriculum to their needs. They wanted practical help in implementing approaches which they had never seen or experienced. The first stage of growth emerged as teachers acquired enough confidence to try something new and not be overly worried if it did not work perfectly. In the second stage, teachers realized that they did not know enough to teach in the new ways. The Workshop spent considerable time helping teachers acquire relevant background knowledge. In the third stage, teachers’ growing interest in and understanding of children and their expanding subject matter knowledge merged into the concept of curriculum building. Topics that seemed excessively theoretical at the beginning of the experiment—what children are like, what subject matter and activities further their growth—came to seem relevant and timely as teachers worked with Bank Street staff to create a system-wide social studies
curriculum. In the fourth stage teachers began to relate their job to broader social problems in the world.

The Bank Street Workshop exhibited many of the features currently associated with effective professional development (Borko and Putnam, 1996; Knapp, 2003; Wilson and Berne, 1999). By documenting the practices of the Workshop as well as its impact on teachers and on the learning opportunities they provided to students, *Our Children, Our Schools* also offers an early example of research on teacher learning through professional development. Finally, Mitchel’s analysis of how the hierarchical school system worked against the formation of self confidence, intellectual curiosity and professional judgment foreshadows recent efforts to document the impact of school cultures and structures on teacher’s stance toward teaching and their own learning.

The third artifact, “The Nature of Expertise in Teaching,” illustrates the influence of cognitive science on the study of teacher learning and the value and limits of efforts to describe stages of teacher development. (For reviews and critiques of this work, see Feiman-Nemser, 1983; Grossman, 1992; Richardson and Placier, 2001.) Written by David Berliner and organized around seven propositions, the chapter reviews studies that compare the thinking of novice and expert teachers in order to generate “a deeper understanding of the sophisticated forms of pedagogical knowledge used by expert teachers to accomplish instructional goals in the complex social environment called the public school classroom.” By detailing differences in the way expert teachers “read” classrooms, interpret problems, and frame responses to students, these comparative studies demonstrate that accomplished teaching takes time to develop. Although the research does not tell us how novice teachers become competent performers or how competent performers become experts, it demonstrates that even well-started novices cannot have the flexibility or practical knowledge of a master teacher.

One proposition states that experts develop routines to deal with repetitive aspects of their work. Berliner speculates that routinizing certain teaching functions like taking attendance, handing out paper, reviewing homework frees the teacher’s mind to focus on other aspects of the situation, to be flexible, even opportunistic in responding to students’ comments and questions. What emerges is an image of the expert teacher as an “improvisational performer” able to draw connections between students’ questions and comments and the goals of the lesson. This fits with more recent discussions of teachers as “adaptive experts” able to balance efficiency and innovation (Darling-Hammond and Bransford, 2005).

While efficiency and innovation may be complementary, it is also true that well-learned routines can be difficult to unlearn and may prevent teachers from experimenting with new approaches or responding in flexible ways to unanticipated situations. What kind of teacher preparation lays a foundation for the development of adaptive expertise in teaching? What kinds of working conditions and professional learning opportunities increase the likelihood that advanced beginners will become competent performers and that competent performers will develop proficiency and even expertise? Ultimately these questions call for longitudinal research that traces teacher learning across the multiple settings where teachers learn to teach and develop their practice. Such research can shed light on how and why teachers adopt particular ways of thinking and acting in response to the realities they face in a given setting and how, in the process, they form a sense of themselves as teachers.
Commentaries

The three commentaries open up the discussion of teacher learning from multiple perspectives. Teacher/scholars Vivian Troen and Katherine Boles draw on years of co-teaching in public schools and continuing work in teacher education to reflect on teaching and teacher learning from the inside. The Learning/Teaching Collaborative which they founded and which they describe fits well within the progressive traditions represented by Dewey and Mitchel. Renée Clift, experienced teacher educator/researcher, takes a different tack, highlighting some of the pressures and challenges researchers face in forming research teams and designing longitudinal studies of teacher learning. She calls for a different kind of doctoral training for those who aspire to an academic career, including exposure to a broader set of research models and paradigms. Daniel Fallon, architect of Teachers for a New Era, observes that the research literature on teacher education and teacher learning is “richly endowed with normative and logical arguments,” but lacks “empirical evidence to support a program of teacher learning.” Nevertheless, Fallon is optimistic about the prospects of financing sophisticated empirical research on teacher learning that uses student learning as the measure of effectiveness.

Expanding demands on America’s teachers and the centrality of teacher learning in serious efforts to improve the quality of teaching have led to increased interest in research on teacher learning. Researchers are investigating teacher learning in intentional settings like teacher preparation and professional development, and studying the influence of collegial interaction on teaching and teacher learning. We have some evidence that high quality preparation, induction and professional development can promote changes in teachers’ knowledge, skills and dispositions. We also have evidence that it is easier to become a good teacher in schools with a collaborative culture. Still, we know little about what teachers actually learn in reform-minded and traditional programs, why particular activities promote teacher learning, what enables teachers to act on what they have learned, how teacher learning contributes to student learning.

We need more conceptual work on the content, mechanisms and contexts of teacher learning, more longitudinal studies of teacher learning over time, more attention to the learning of teachers with different cultural and educational backgrounds, and more thoughtful efforts to link teacher learning to meaningful student learning. As Wilson and Berne (1999) conclude in their review of research on teacher learning and the acquisition of professional knowledge, “The future of good research on teacher learning lies in our ability to weave together ideas of teacher learning, professional development, teacher knowledge and student learning—fields that have largely operated independent of one another” (p. 204). The quality of teaching and learning in our nation’s schools depends on it.

The metaphors by which we teach

Experience, metaphor, and culture in teacher education

Cheryl Rosaen and Susan Florio-Ruane
Michigan State University

Humans do not converse because they have thoughts to express, but they have thoughts to express because they converse.

INTRODUCTION

In this chapter we examine a topic of perennial interest in teacher education: the role of experience in learning to teach. Rather than reviewing a particular literature dealing explicitly with the topic, our point of entry is “metaphor,” a process comparing one thing to another that is used not only by poets, but by all of us—tacitly and explicitly—to weave individual with society, experience with concept, and word with activity. Building upon work of linguists who investigated the relationship between metaphor and thought (e.g. Ortony, 1979/1993), Lakoff and Johnson (1980) argued, “metaphor is pervasive in everyday life, not just in language but in thought and action. Our ordinary conceptual system, in terms of which we both think and act, is fundamentally metaphorical in nature” (p. 3). In these ways, metaphors are central to how we experience and understand the world because they provide an experiential framework for making sense of abstract concepts. We often experience one thing in terms of another.

Connecting the ideas of metaphor and experience with teaching, learning and teacher education is not new. Some scholars have used metaphors descriptively to help us understand classroom life by characterizing teachers as supply sergeants, traffic cops and time keepers (Jackson, 1968) and by identifying roles for teachers such as executive, therapist or liberationist (Fenstermacher & Solis, 1986). Others have investigated what metaphors reveal about beginning and experienced teachers’ conceptions of teaching and their emerging sense of self (Bullough, 1991; Bullough et al., 1991; Bullough & Stokes, 1994; Grant, 1992; Munby, 1986; Munby & Russell, 1990), and the images that guide their actions (Clandinin, 1985, 1986). For example, knowing that some teachers see themselves as a “butterfly” or “chameleon,” or conceive of their role as that of “parenting,” provides insights into how they view the work of teaching, and allows us to explore whether their conceptions change and evolve over time (Bullough, 1991). Exploration of teachers’ metaphors for teaching can help us understand the conceptual systems that guide their work (Berlin, 1990; Collins & Green, 1990; Cohen & Lotan, 1990; Shuell, 1990). Some teacher educators have taken the concept of metaphor a step further and used it as a heuristic to get preservice teachers to be more reflective (de Guerrero & Villamil, 2002; Hunt & Gow, 1984; Marshall, 1990; Tobin, 1990; Weade & Ernst, 1990) and to help collaborating teachers learn productive ways to talk with student teachers (Carter, 1990).

In this chapter we investigate metaphors and learning from experience from a slightly
different angle. We take a close look at how metaphors that are pervasive in our culture and profession have the potential to influence how preservice teachers make sense of their experiences in teacher preparation programs and classrooms where they learn to teach. We argue that metaphors, if left unexamined, have the potential to limit or constrain what novices learn from experience.

The chapter is organized into four sections. The first section, *Experience and Learning as Social Processes*, discusses theories of experience and learning as social processes, pointing out the importance of language in mediating stimuli and developing concepts. We show how people use language to describe activities and to make of them what Dewey (1938) called, “educative experience.” It is through the use of figurative language, which is culturally patterned and shared, that people learn actively and form concepts and networks of concepts. We draw on the work of Soviet psychologist Vygotsky (1981), who studied learning in the context of social interaction, and argue that people develop understandings in social interaction with others and, in this way, thought begins on the social plane before becoming internalized on the individual plane. Metaphors we use to represent our experience help us know what we are experiencing, which is why study of experience is important to the education of a teacher.

In the second section, *Understanding Experience through Language, Metaphor and Representation*, we draw on the work of Lakoff and Johnson (1980) and Donald Schon (1979/1993) to focus on metaphors as one form of representation that is often hidden and embedded in our everyday language. We explain how different types of metaphors influence the ways in which we experience the world. Three common metaphors found in educational discourse are examined: field experience; struggling readers; and at risk learners.

“Field experience” is examined as a root metaphor that is so embedded in the language and culture of teacher education that we often do not recognize it as a metaphor at all. It is a root metaphor from which other metaphors spring. We argue that this metaphor influences how teacher educators conceive of and organize university- and school-based experiences for novices. An alternative metaphor, ecological environment, is explored in terms of its potential for reinventing the social dimensions of learning to teach.

The second metaphor, “struggling reader,” was selected as an example of an ontological metaphor. An ontological metaphor takes an abstraction (how one experiences learning to read) and expresses a certain version of that experience (a great deal of effort may be put forth by the reader without success) as a certain type of person (struggling reader). Because reading is so central to all learning, and because metaphors like this are found in common parlance and in professional discourse, it is important to consider how metaphors of this type position learners and where they focus novices’ attention.

A third metaphor, “at risk learners,” was selected because it is another example of an ontological metaphor (the abstraction of danger and threat are expressed as a certain type of learner). It also illustrates what Schon (1979/1993) calls a generative metaphor. Generative metaphors suggest a particular way of looking at a situation (i.e. there is a danger or threat to our educational system when the number of certain types of learners increases) and that way of seeing the world or framing a problem suggests (or generates) its own solution (i.e. fix what is wrong with the learner and the danger/threat will go away).

Thus, the second section illustrates how these three common metaphors are used in teacher education and in teaching to represent complex ideas by associating them with the familiar. We maintain that these metaphors can limit how beginning teachers make sense of experience and what they think is possible to attain. In addition, we argue that as conceptual networks of terms used in common parlance make their way into professional
conversations, teacher educators and beginning teachers alike are in danger of falling prey to them instead of learning from them.

In the third section, *Teacher Educators as Designers of Experience*, we suggest both a means and an end for re-considering the metaphors embedded in our language and culture, and for recognizing how teaching and learning need not be limited to what we can know by means of extant, culturally patterned, and largely tacit representations. We imagine a new metaphor, teaching as weaving, that brings into consideration multiple layers and dimensions of teaching, learning, and learning to teach. This metaphor suggests new designs for teacher education. We draw on our own work in teacher education and the work of others to provide examples of pedagogical tools and practices for helping novices develop explicit metacognitive awareness of the ways educators, politicians, and the general public use their implicit theories to interpret experiences. We argue that awareness and understanding of the metaphors by which we teach—their stability as well as their contingent, situated nature—is fundamental to thoughtful practice and also to the beginning teacher’s educative experiencing of that practice.

In the final section, *Where Does Understanding Experience, Metaphor and Culture Lead Us?*, we identify questions for future research. For example, we call for investigating the extent to which beginning teachers’ explicit examination of metaphors that are pervasive in our profession and culture influences what they pay attention to as they experience various aspects of teacher preparation. We also call for empirical study of the alternative metaphors for designing and redesigning teacher education offered in the chapter—the field as an ecological environment, and teaching as weaving—to understand more fully what contribution they make, if any, to creating alternative structures for social interaction and transforming our own practices as teacher educators.

**EXPERIENCE AND LEARNING AS SOCIAL PROCESSES**

Experience pervades everyday life, and we all learn by means of our cultural transactions within it. Our encounters with the social and natural world are woven into meaning by language. Accordingly, cognition and culture grow for the beginner and also for the community of which he or she is a part. For example, when a grandfather walks with his young grandson and a hairy, four-legged creature approaches them wagging a tail, the child may shout, “Max!” In response, grandfather is apt to say something like, “Yes, this is a dog and you have a dog, too. Your dog is named Max.” In this exchange so much has happened by way of the linguistic mediation of experience and the authentic engagement of a more and a less experienced member of the culture. Most important perhaps is that in the intimacy of adult-child interaction, language and concept development proceed almost incidentally, and context is immensely important to the process. Initiates’ repertoires for speaking and thinking about complex ideas are limited. But with growing interaction within the physical world and among experienced members of a culture, beginners’ thought and language become increasingly complex. Vygotsky studied learning in the context of social interaction, and he referred to this linking process as “inner speech.” He asserted that, “any function in children’s cultural development appears twice, or on two planes. First it appears on the social plane ... Social relations or relationships among people ... underlie all higher functions and their relationships (Vygotsky in Wertsch (1981, p. 163), cited in Cole 1996, pp. 110–111). Ultimately, thought, which began on the social plane, is internalized and personalized in cognitive networks of words, ideas, and experiences, which have been learned and have meaning in the company of others (Vygotsky, 1981).”³
Learning to teach as situated activity

What in large part makes the teaching profession and the process of learning to teach different from everyday life among youngsters is that prospective teachers engage in various planned activities in classrooms such as observing, planning and teaching lessons, assessing learners, and talking with mentor teachers. Some, like Dewey (1915, 1938), would not even call being swept along in the flow of classroom talk or activity a learning experience—not unless it was social, authentically oriented to a purpose, and guided with curricular ends in view. In fact, Dewey was the first philosopher to stress the importance of situation to learning and to presage the idea that situations or contexts are not the theater sets on which life is enacted. Situational contexts are, in fact, made up of an array of props, tools, artifacts, and message systems that we take for granted. For Dewey, the situation, as it was co-created in classroom activities and guided by the teacher toward curricular “ends-in-view,” was the key linkage of language, experience, and the development of thought.

We know that experience is hard to recognize precisely because we make it, and tacitly, we take our message systems for granted. Sometimes it takes a breakdown in our assumed common understanding to find that while we have a consensus that is workable generally, not all members of the community think the same way. Oftentimes, for instance, teacher educators’ ideas about fruitful experiences differ from our students’ expectations of what it takes to learn to teach. Consider, for example, what Lana, a senior in a literacy methods course, had to say about an assignment that required her to plan, teach and reflect on a language arts lesson in an elementary classroom: “Real world experience is the best kind!” And about course reading assignments Lana commented, “I feel that experience is more helpful, but the readings were a good place to start.” We see that while reading has some value to her as a launching point for her learning, getting “real world experience” in learning to teach is most important to her.

Considering Lana’s comments in rhetorical terms suggests the question: What is implied by the terms “real world” and “experience”? Metaphorically, the “real world” is located in elementary classrooms, not in the university classroom or at Lana’s apartment while she reads. “Experience” in elementary classrooms could mean many things to Lana that may or may not foster her learning: participation; imitation through apprenticeship; trial and error experimentation; discovery; implementation of methods for teaching literacy, and so on. While the sense of the authority of experience persists for Lana and many teacher candidates, the question of what and how novices actually have opportunities to learn from experience is important to consider (Feiman-Nemser & Buchmann, 1985; Munby & Russell, 1994).

Learning to teach in “activity settings”

Scholars have argued that carefully designed experiences in classrooms have the potential to help novices go beyond having experiences to helping them learn from them by developing their abilities to perceive and assess a classroom situation, make judgments, formulate goals, choose a course of action and reflect on consequences (Dewey, 1904/1964; Kennedy, 1987, 1999; Kessels & Korthagen, 1996; Schon, 1983, 1987). For the practicing teacher the tools that are used to prepare and enact learning experiences are both practical and conceptual (Grossman et al., 1999). According to socio-cultural theory, learning to teach takes place in various “activity settings” that contain tools, artifacts and message systems. Conceptual tools include the guiding principles, frameworks, and theories that help teachers interpret their practice and make decisions.
These include broad concepts such as adopting a diverse social constructivist orientation (Au, 1998) as well as ideas that fit with a particular stance such as teaching for social justice (Ayers et al., 1998; Cochran-Smith, 1998), culturally relevant teaching (Ladson-Billings, 1995), or critical and feminist pedagogies (Gore, 1993). Practical tools include the resources and teaching ideas used in daily teaching (Grossman et al., 1999). These consist of knowledge of curriculum materials and pedagogical and assessment strategies that enable teachers to provide instruction that is responsive to a range of learners (Au, 1993; Villegas & Lucas, 2002).

From this viewpoint, concepts and theories are not learned as ends in themselves. Novices require support in learning to use them interpretively as instruments to explore their perceptions, generate questions, examine points of view or arguments, and make judgments about means and ends. As they gain language for communicating about their work, novice teachers begin to see that their craving for experience-as-action is necessary but not sufficient for learning to occur. Beginning teachers must temper the tendency to describe and understand their work with pupils as exclusively a matter of “doing.” They also “do” in their planning in the empty classroom after their students have gone home at the end of the day. And, as we have already noted, learning in teacher education involves a variety of experiences and so must entail both kinds of doing—“hands on” teaching and analytic work that includes talking about and writing about ideas with others. Consequently, in order to learn from experiences, beginning teachers need both analysis and action in order to see the connections between the two (Dewey, 1904/1964; Kennedy, 1987).

This is why penetrating study of experience—not only study by means of having experience—is important to the education of a teacher. This kind of study is not merely a matter of learning the ordinary. It is learning to understand one another’s understandings, since even the same word can function metaphorically, yet in different ways, depending on the perspective, prior knowledge, purposes and role of the speakers. This in fact exemplifies the situated nature of metaphors and how they help us understand complex ideas such as “real world,” “experience” or “learning.” If we are aware of these ideas and learn with and from one another about such differences, we are engaging in an aspect of learning to teach that is not easily observed but fundamental to good teacher education.

UNDERSTANDING EXPERIENCE THROUGH LANGUAGE, METAPHOR AND REPRESENTATION

Experience is expressed metaphorically in ways so common that they and their meanings can become tacit, and widely held as local or “folk” knowledge (Geertz, 1983; Bruner, 1996). Much of this knowledge derives from metaphors of place and movement, or what Lakoff and Johnson (1980) refer to as “orientation metaphors,” which are systematic and organize “a whole system of concepts with respect to one another, and have a basis in our physical and cultural experience” (p. 14). An example familiar to most of us is the metaphor “sunrise.” Because orientation is a common, shared phenomenon, we know “rising” as going upward, as when we awaken and rise from our beds. We can talk of the sun similarly “rising,” because it changes in orientation from below the horizon (having previously “set”). Even though the sun does not literally rise and fall relative to us, the metaphor is resonant with our immediate experience of position. It also extends to a network of related associations—we lie down at night just as the sun sets to give us nightfall. We awaken and rise at sunrise, and we think of dawn as a time of revival after sleep.

This metaphor powerfully organizes how we think about daily cycles, cycles in nature,
and life cycles. We die and are placed in prostrate positions down in the ground. But many believe that we rise—as in the Christian resurrection—and, like the sun, ascend into a high place we might call heaven. Few of us stop to think about all this when we get up in the morning or even when we note the beautiful “sunrise.” Fewer still connect this discourse with formal study of astronomy or physics. There is no need for most of us to do so, because meaning need not be “true” to be sensible and shared.

Metaphors simplify and are selective; this is at once their power and problem. Simplifications can make it easier to view aspects of a complex phenomenon—but they do so by framing out of view other aspects which, had they been included, might change an image entirely. They also caricature, exaggerating some features to make them more salient and easier to view. But what we may get is a distortion, not an enhancement. Finally, metaphors offer enticing—and confusing—multiplicities. Some can turn on a tiny detail in the reading of a situation, while others depend on perspective or position.

When, for example, we also extend orientation metaphors to social relationships, we do more than wax poetic or reveal lack of knowledge of astronomy. Unaware, we can characterize learners, for example, in ways that are damaging to them. Consider that teachers sometimes refer to the “low” readers in their classrooms and restrict access to rich learning materials for that population, based on the assumption that low readers are incapable of learning from complex texts. Or a teacher might say that a student doesn’t want to “aim high” and settle for minimal performance as good enough for that learner’s goals. Teachers might want to encourage their students to “raise their grades” and foster inadvertently a misplaced focus on extrinsic versus intrinsic rewards. In other words, educators might assimilate such ways of speaking and thinking without awareness and critical reflection. Used by teachers, such metaphors transcend the vernacular and have the power of a profession behind them. Thus metaphors may not only limit understanding, but may also limit opportunities for students to learn. Below we consider three metaphors that, left unexamined, have the potential to shape how we organize experiences for beginning teachers and influence the systems of thought that guide our work as educators: “field experience,” “struggling readers,” and “at risk learners.”

“Field experience”: an unexamined root metaphor

As we pointed out earlier with Lana’s comments, when asked to evaluate their program of study, new teachers are apt to report that they learned little from their university courses but a great deal from their “field experience.” While teacher educators cringe at what seems to them to be a reductive model, a second look at the term and its use by students of teaching is revealing. “Field experience” in teacher candidates’ lexicons is what linguists call a “root” metaphor. Root metaphors are embedded in our language and culture and thus are often overlooked as metaphors; they also spawn other metaphors. There is a clear and fundamental physical connection between “field-as-place” for growth and nurturance, but it is also a metaphor connected to place in the sense that the classroom is itself a place. Ironically, though their instructors may miss this aspect of beginners’ ways of representing learning to teach, it is for teacher educators part of a hybrid of meanings linking “hands on” and “real world,” but also a metaphor that abstracts from physical place to “discourse-as-place.”

Different “activity systems” for course and field work

Thus teacher educators do, in fact, place a great deal of time and emphasis on students’ observation of and work with children and teachers in schools. But we take pains to
accompany the pragmatic “hands on” with thought about activity—and with thought about the concepts such activity might help students to develop. These activities are linked metaphorically to the field in the sense that a professional field is a sociolinguistic place—and identity—that includes speaking, thinking and understanding as well technique.

Nevertheless, it is commonplace to speak and act in ways that differentiate between field experience as one activity system and university coursework as yet another activity system. We lend “experiential” status to the former and run the risk of separating doing from thinking in the latter. We also run the risk of reifying this representation when we create very different activity systems for learning in each context. These activity systems differ in participants, speakers’ rights, social roles, ways of speaking, tools, artifacts, purposes, and physical settings. For instance, in teacher education course work we tend to focus on the conceptual tools associated with teaching; reading about and discussing theories and concepts; writing analytic papers that help teacher candidates make sense of theories and concepts; and talking about appropriate teaching methods that are consistent with the theoretical orientations featured in the course. Opportunities to “use” or “apply” these concepts and ideas—through the use of practical tools—occur in “the field” where teacher candidates select resources and methods to design and teach lessons to “real” children in “real” classrooms. Subsequently, reflection on these “real world” experiences takes place away from the field—by writing a course paper, or by engaging with peers in discussions back on campus. Only recently have some teacher educators begun to hold their teacher education courses in schools where the lines between learning versus doing and the theoretical versus the practical can be blurred more easily. Even then, however, the activity settings for course work (e.g. reading, writing, discussing the literature in a room where adults gather) versus the “real work” of teaching in the classroom (e.g. interacting with children using educational resources) remain strikingly different. As a consequence, our students quite appropriately divide their professional education into two unrelated parts as they are expected effectively to change discourses and cross culturally determined borders in order to learn.

Field experience and the “hidden curriculum”

There is a powerful “hidden curriculum” (Jackson, 1968) in the field experience metaphor. That is, there are things outside the stated objectives of a given teacher education program or course that prospective teachers learn as they prepare for practice by coming to campus and going back to the school. They experience learning largely on their own by being “placed” individually with one collaborating teacher. This learning is different from what they are able to get from studying theory by reading about it in articles and books. For instance, beginners learn to see teaching as isolated within a classroom with a closed door (Jackson, 1968; Lortie, 1975) and compartmentalized within grade levels or subject matter departments (McLaughlin & Talbert, 2001; Siskin, 1994, 1995). The meaning being the message, beginning teachers may personalize problems, hold themselves to unrealistic standards of knowledge and performance, blame themselves when difficulty arises, and make (or abandon) the crossing from the student to teacher essentially alone (Britzman, 1991). These are not planned as learning outcomes for beginning teachers, but nevertheless represent how some novices experience “the field.”

Positioning the field as a more productive learning environment

Thus, field experience is a metaphor that links two ambiguous terms into a unified, comprehensible object. It is an accessible way of speaking about a complex educational
accomplishment involving multiple sites, situations, ways of speaking, and social roles. At the same time, the metaphor effectively sets up the experience of many teacher candidates as learning little in one setting and a lot in another. It contrasts the outdoors, green and growing, with the enclosed, remoteness of staying inside. We are physically more constrained indoors. We are active outdoors. The air is stale indoors but fresh outside. We think within but act without. Hands on, experience-based, practical, and real all associate with the word “field,” as does tilling soil, growing, and nurturing. Indoors we mind our manners, speak more softly and have little connection with nature. Our indoor environment is ornamented by material objects—irrelevant to our growth and survival. In nature, we are encompassed by a powerful life force we cannot tame but of which we are a part.

Thus we see the power of familiar associations is such that we organize institutions, activities, tools, language, and social identity in ways that reinforce them. The metaphor is sufficiently useful in its simplicity that it becomes part of our stock of common knowledge. Yet, as Scribner (1984) found when she studied metaphor in literacy education, its very shared, simplified characteristics limit possibility and leave us mostly trying to refine, assess or otherwise modify what we have come to know rather than thinking about how else experience might be understood. Scribner argued for literacy, as we argue here, that simplifying metaphors for variable, situated activities invites thinking of activity as object rather than a process and the individual as a recipient rather than a co-creator of experience and learning.

Examining an alternative metaphor to envision enhanced social interaction

Looking closer at the metaphor and interpreting rather than living by it, we can see how it shapes meaning—and also how it might be re-thought—in freeing, critical ways. If, for example, we re-think the field as a metaphor, we might compare education to the field as an ecological environment, and find ourselves conceptualizing experience and learning in very new ways. With the ecological environment metaphor we note, for example, that growth involves interdependence as well as interaction among organisms. Thinking of the field as an ecological environment, teacher educator, teacher candidate, and practicing teacher work together to make meaning and depend on one another to do so. From this view, teacher educators would not dismiss the ways today’s practicing teachers mediate the daily challenges they face in their classrooms—such as preparing students for standardized tests—as “maintaining the status quo” or “teaching to the test.” Instead, they would encourage teacher candidates to ask questions so they can understand how these challenges become powerful forces that shape teachers’ everyday practice. In this way, the practicing teacher provides access for both teacher educators and prospective teachers to the complex context in which novices learn to enact their practice. That same teacher also shares ways in which she manages the tensions and dilemmas in making curricular decisions that fulfill school and district mandates while also following her professional judgment regarding what constitutes good teaching (e.g. Johnson, 2001; Lampert, 2001). Subsequently, both teacher educators and practicing teachers share responsibility in helping teacher candidates see and understand the forces that shape the teaching context.

By rethinking the field as a metaphor we also contemplate the balance of diverse ingredients needed for growth. As we have seen, ingredients for teaching and learning include conceptual tools, such as theories and concepts used to guide and interpret practice, as well as the practical tools familiar to teachers’ daily work, such as curriculum
materials, textbooks, trade books, math manipulatives, or microscopes. Working with conceptual tools without consideration of the practical tools needed to plan, and teach lessons or assess learners’ progress has the potential to make those tools seem distant, or even irrelevant to the real work of teaching. On the other hand, only working with practical tools without consideration of guiding principles and theories can reduce practice to implementing a series of “fun” or “neat” activities that may not lead to educative experiences for children and may not help the beginning teacher understand whether or why certain practices are effective. Teacher educators, beginning teachers and experienced teachers all play a part in working with, and talking or writing about the tools. That is, if we separate these ingredients from one another or an organism from the ecology, we risk the growth of the individual and also the growth and health of the community.

Reading “field experience” this way, we see the social dimensions of learning to teach include enacting practice and analysis of practice through conversation and writing. We also see the necessary interdependence of a variety of experiences, and the cultural nature of experience in root, radical terms—culture as in agriculture—as the nurturing of the young plant into maturity. Teacher educators, teacher candidate and practicing teachers all play a part in this interactive, meaning-making process.

“The struggling reader”: metaphors as powerful organizers of experience

Shared metaphors develop shared concepts and systems of thought (Lakoff & Johnson, 1980). These systems quickly become sedimented as they shape subsequent activity and understanding and are passed on. In effect, they become phenomena. Largely taught and learned in ordinary situations, metaphors and the concepts they engender are often tacitly held. And, as Bruner (1996) observed, as local or folk knowledge, they do not require empirical testing to be taken as true. They are believed to be explanatory and predictive and this believing makes it so. We learn that grandfather’s aching toe predicts a coming storm. We do not question how and why “it works.”

Much has been written in teacher education about the intrinsic difficulty of making what has become a familiar context (with shared and taken-for-granted ways of speaking, acting, participating, and thinking), the classroom and school, into a newly unfamiliar one. To become a professional educator the student must see, hear, feel, speak, and learn from familiar stimuli in new ways (Florio-Ruane, 1990; Frank & Uy, 2004). This is a cognitive change very closely tied to communication. Teachers’ language and metalinguistic awareness are extremely important aspects of their professional education and practice. Critical awareness of language—its forms, functions, and power to shape activity, learning, and learners—is perhaps the most important and most difficult task of becoming a teacher, yet it is something teachers must learn in order to teach it to their students.

An ontological metaphor categorizes learners

Consider, for example, the metaphor “the struggling reader.” As discussed in this chapter’s introduction, this is an ontological metaphor that takes an abstraction (how one experiences learning to read) and expresses a certain version of that experience (a great deal of effort may be put forth by the reader without success) as a certain type of person (struggling reader). The popular media and the ordinary citizen may freely speak of struggling readers. Unless they are teachers, however, most have little influence on
reading education and little more than passing interest in the topic. There is nothing to cause these speakers to pause and think about their words. They rarely ask, “Why do I associate struggle with reading?” or “With whom or what is the reader struggling?” and “What does it mean to characterize someone as struggling?” or “How did I decide whom to label that way—and why?” (Florio-Ruane & Raphael, 2004; Rogoff, 1990).

So we see that when beginning teachers spend time in local classrooms and gloss a child or group of children as “struggling readers,” they are using a metaphor available in both common parlance and in teachers’ talk. These teachers must learn that the term is being used, however, inappropriately to construct difference as a deficit within individual readers; this construction runs the risk of missing other issues that require attention, such as structural or institutional inequalities that may contribute to whether or not a given group of students is learning to read at a desired rate (Gutierrez & Orellana, 2006). In a chapter titled “Struggling and Difficulty in Reading: Managing Vulnerability,” two experienced educators, Randy and Katherine Bomer, engage in an important analysis of how the “struggling reader” metaphor positions children:

Who is the struggling reader? The term itself is suspect, since it implies that all struggling readers belong to a single category. Anyone can struggle, and no one struggles all the time. No two readers struggle in the same ways. A poor score on a test may mean simply that a reader struggles with tests, not with reading something she is interested in. Often the perception of struggling is not coming from the reader at all, but from grade-level expectations or similar setups of the system.

(Bomer & Bomer, 2001, p. 89)

These authors go on to acknowledge that some students do not learn to read without struggling with some aspect of the process but they are careful to point out that different readers wrestle with different aspects of making meaning from text. They also point out that struggling is not the same thing as failing, since, “Struggling implies trying, intentionally putting forth effort. When we watch readers in trouble, we see them struggle. Struggling implies that the effort is unnecessarily great, that reading should be easier and more energy efficient” (Bomer & Bomer, 2001, p. 89).

This analysis points out the pitfalls of importing folk knowledge into professional discourse and using the shorthand of metaphors in technical ways to describe students as all fitting into one single category. The use of one single category provides a false sense of confidence that there is one way to help that category of students, when any experienced teacher would readily dispute that claim. Yet this is a subtle distinction since it is human nature to think we know something because we have a way of speaking about it. This shorthand feature of metaphor is troublesome for the same reason it is useful: in simplifying, it focuses on the individual and takes both the reader and reading as isolated and isolating. Consequently, reading and learning to read are not viewed in social perspective.

Moreover, the “struggling reader” metaphor relates closely to the orientation metaphor of reading development where “We think of a line on a graph that shows nothing but profit, continual improvement in a given direction. When we see readers struggling, we imagine that they are at a lower point on the line than those who don’t struggle” (Bomer & Bomer, 2001, p. 96). This feeds into thinking that there is one process called reading and a single path to learning to read. Those who are not as far along the path are viewed as deficient.
Learning to analyze assumptions embedded in language

Beginning teachers can learn to think critically about the talk they hear among the general public and educators in schools by playing what Elbow (1986) calls the “believing game” and the “doubting game.” He describes these processes as disciplined approaches to (a) working to “believe” particular interpretations, even when they don’t easily fit with their presuppositions in order to understand them thoroughly; and (b) working to critically and systematically “doubt” or appraise underlying assumptions. Elbow explains,

As intellectuals we need to learn to doubt things by weaning ourselves from ideas, particularly our own. We need to learn how to cease experiencing an idea while still holding it, that is, to drain the experience from an idea and see it in its pure propositionality . . . Methodological doubt represents the human struggle to free ourselves from parochial closed-mindedness, but it doesn’t go far enough. Methodological belief comes to the rescue at this point by forcing us genuinely to enter into unfamiliar or threatening ideas instead of just arguing against them without experiencing them or feeling their full force.

(Elbow, 1986, p. 263)

It is important to make explicit the metaphors we take for granted and look closely at the concepts and ideologies they support. Using Elbow’s approach, rather than throw out entirely the word “struggle” from their vocabulary (and thus only “doubting” its merits), beginning teachers can learn to distinguish categorizing students (as struggling readers) from describing readers’ experience (noting how a particular reader struggles with a particular aspect of the reading process). This subtle distinction shifts the novice’s attention from thinking of those who struggle as being all the same to focusing on identifying individual learning needs. A professional educator is expected to ask these questions precisely because he or she has rhetorical force by virtue of professional identity and status. As a gatekeeper, what a teacher says about a child who is learning to read can make an enormous difference in that child’s educational biography and life chances.

A key point here is that the language teachers and other professionals use to describe and interpret those in their care and the meanings they make of their own lived experiences can distort, alienate, silence, and preclude examination of what others find uncomfortable or threatening. But metaphors are taken up precisely because they “work” by simplification, association, and giving members of a community a handle on—or shorthand for—something complex. We assume these tools enable us both to understand complexity and hold that understanding in common. Because professionals have often found that it is difficult to break the frames accepted in their extant discourse communities, it is necessary to step outside a familiar discourse in order to look at it critically and see it as contingent. Our familiar discourse can sustain and enable practice or it can truncate it.

“At risk learners”: metaphor, ideology and power

By stopping to think about the metaphoric nature of our descriptions and the power we as teachers have to describe, we can see our practice as far more than a pragmatic exercise in prediction and control. The agency teachers have in this transformative work is considerable. It is also ideological. This aspect of teaching does not come naturally or easily. It needs to be taught, learned, and practiced (Shannon, 1992). Moreover, an important part of the professional’s work is, according to Cochran-Smith, “taking account of the
ways metaphors, narratives and literary devices are used strategically to garner support for the approaches various groups favor and also for their ways of understanding the issues in the first place” (2005, pp. 4–5).

Viewed this way, neither our talk nor our actions as teachers and teacher educators are, again quoting Cochran-Smith, “politically neutral.” Our work is intrinsically ideological and undertaken in the crucible of culture, where ideologies intensify and harden in the heat of discourse. By the same logic, “experience” is not neutral and, thus, learning, too, is ideological in nature, serving to enhance our understanding of nature and human society but with particular ends-in-view. Teaching and teacher education are of necessity pragmatic enterprises. But a learning environment which tends to operate in terms of the “what” and the “how” to the exclusion of the “why” and “wherefore” can become reductive, reproductive, and mute. Thus, understanding the cultural and historical origins of metaphors can provide insight into their political and ideological power.

**Metaphors make their way into our common stock of knowledge**

In Biblical scholarship there is a Greek word standing in tension with “chronos.” We understand that chronos refers to the experience of time, one instant after another. We live primarily in chronological time and mostly tell stories (even if they contain flashbacks) chronologically: “And then what happened? What happened after that?” This way of experiencing time, language, and activity tends to limit our seeing to one dimension, to chains of cause and effect, to sequences that, though unique in content, are repetitive in form and function.

Kairos, in contrast, is quite another kind of time. It is not clock-time but interruption of it—another kind of time where we are called to act, think, or speak in a different way from the usual. This change in the nature of our language and relationships is referred to rhetorically as “kairos.” This is the Greek word for “opportunity,” “occasion,” or “turning point” (Erickson, 2004). It can be invoked by powerful people and interests, but it is also the province of all members of a culture; it is one way that people can shape as well as be shaped by culture (Eisenhart, 1995). Especially at times of major significance, change or crisis in the wider society, professionals, such as teachers and teacher educators, are called into question in ways that affect their organization, knowledge base, activities, and professional education. Because teaching is a public, applied profession, examination and reform of practice takes place both inside the practice and outside it. When people believe that education is failing society or that society is failing and education is a likely solution, the profession emerges as a focal point of public debate and discussion. Increasingly central to the debate at such times of apparent crisis are the preparation of teachers and assessment of their mastery of specialized knowledge and their competence effectively to practice their craft.

Thus, the metaphors dominating the national discourse about education, teaching, and teacher education are not so much imposed deliberately by virtue of some kind of power (political, economic, spiritual, etc.), but instead are circulated or seeded in the common cultural ground through every day discussions among the citizenry, news reporting and dialogue among professionals. As metaphors are taken up, even for purposes of rejecting, critiquing, or debating them, they find their way into the stock of common cultural knowledge, preoccupying and shaping subsequent thought and speech.

**“Generative” metaphors suggest their own solutions**

For example, it is not uncommon for a teacher (experienced or beginner) to speak of a child as being “at risk.” The visibility and conceptual ante was raised on this metaphor in
1983 when the Federal government issued a report titled “A Nation at Risk” (National Commission on Excellence in Education, 1983). Calling a crisis in U.S. public education relevant to competitiveness in a global economy, the report used “risk” to evoke a sense of danger and to describe the likelihood of failure or of the nation being overcome. Like the “struggling reader,” the “at risk learner” is an ontological metaphor that locates the problem within the child, rather than portraying a competent child who is placed in a dangerous situation. This metaphor is also generative (Schon, 1979) in that it suggests a particular way to frame the situation: our educational system becomes more threatened as the number of “at risk learners” increases. Framed in this way, with all the relevant facts apparently embedded within the metaphor itself, the metaphor suggests, or generates, its own solution: fix the learners and the threat will diminish.

For the nation, the risk, too, was internal. Because of falling standards in education, for example, the report described students leaving U.S. schools as not ready to compete successfully in the global economy. Subsequently in the early 1990s, curriculum standards meant to address the identified “risks” soon became standardization, thus extending the network of metaphors that shape experience and the conceptual and practical tools novice teachers have available to them to learn in practice.

As this example illustrates, novice teachers need to develop awareness that the language of others—and others’ interests—shapes thinking and sense-making. In times of crisis, people tend to opt for the simplicity and reliability of hierarchy. Borders harden, and horizontal structures—from collaboration across disciplines to flexible scheduling, or even to school architecture—are set aside. The language of others also shapes the tools that are available to teachers to learn and enact their practice. When curriculum materials, approaches to assessments, and professional development experiences are all “aligned” with curriculum standards for schools and professional standards for teachers, the conceptual and practical tools available to teachers become constrained. There is an implicit message that these tools provide the solutions to “the problem” of “at risk learners.”

Now that the more recent policy No Child Left Behind (2002) has become part of public and professional discourse and teacher candidates, teacher educators, and practicing teachers alike speak of NCLB and nod knowingly, we must acknowledge that rhetorical work has been done somewhere, somehow, and by someone (or some group). And when rhetorical work is examined carefully within the social and historical contexts from which it emerged, we uncover ideological and political stances that have the potential to shape what and how beginning teachers learn from experience.

TEACHER EDUCATORS AS DESIGNERS OF EXPERIENCE

Given the powerful role metaphors play in shaping what teachers perceive and learn from experience, there are important design implications for teacher educators. One way to approach design is to consider an alternative metaphor for educating beginning teachers. We often describe or think of teaching as historically a “woman’s profession” in which craft, relationship, and care are as important as objectivity, reason, and proof. It seems appropriate, therefore, to suggest weaving as a metaphor for teaching since it befits the concepts powerfully associated with our work. It offers alternatives to the rigid, encapsulating metaphors of structure in which we have little apparent means to change our circumstances.

What does this metaphor bring into view? Weaving involves work on multiple levels and in multiple color and tensions. The project is to move among these levels in a creative yet patterned way to make a unified and aesthetically pleasing work. It also can be a
simpler activity in which yarn is strung and repeatedly moved in two directions to make fabric—more intended, perhaps to warm our bodies. In either case weaving has associations that bring together characteristics we often put in opposition: strength and flexibility; structure and agency; individual and collective work; unfolding and design; beauty and utility. Teachers are weavers of meaning in language, by means of experience, in the context of culture, and with their students.

The metaphor of weaving helps us to understand many layers and dimensions of education. Together these layers and dimensions are complex and rich accomplishments. They are learned and taught. Teacher candidates participate peripherally at first but view the expert weaver and the fruits of her labors (Wenger, 1998). They also view the raw material and tools the weaver needs, and gradually they learn to do individually what they could only watch or do with assistance as novices. The rules we frame and follow to make communication possible and allow for its artful improvisational character are very much like the skills, knowledge and creativity of the weaver. They require not only expertise at weaving, but deep understanding of learning to share as educative experience with beginners.

With this metaphor in mind, we can make a different analysis of teachers’ experience and practice. It is not only local and pragmatic, but it is also conceptual and, as such, unfolding. Those who dominate the rhetoric of teaching and teacher education are able to thread their interests strongly into the weave of American education. Ironically, if teachers are not critically aware of the metaphors by which they teach, they cannot speak and see in new ways. If they abdicate the potential of their profession to other speakers, teachers cannot be part of the educational fabric or its weaving, no matter how hard they work or how well they are educated. In helping beginning teachers to make and share educative experience, the teacher educator’s educational responsibility is to support and extend the development of new weavers—who will not only learn the enduring knowledge and practices of a culture, but will transform them as they play with variations upon them, and ultimately as they assume the responsibility of weavers. The examples discussed below provide images of social arrangements and use of conceptual and practical tools that have the potential to guide teacher educators, prospective teachers and classroom teachers in coming to a richer understanding of language, learning and experience in teacher education.

Learning a professional discourse

Examining rhetorical work requires developing meta-awareness, stepping out of our familiar discourse and seeing metaphors as constructs, as examples of many versions of how people have characterized and interpreted experience. A longstanding practice for teacher educators is to work with what teacher candidates bring to their professional preparation: their preconceptions about children, subject matter, schools and schooling, along with their own prior experiences as students. Typically, we design experiences that help teacher candidates make explicit their preconceptions and recount their experiences for closer examination and critique. However, research has shown that these entering beliefs are powerful and difficult to change (Feiman-Nemser, 2001; Wideen et al., 1998).

Pondering the metaphorical nature of language and its relationship to thought in literary analysis, Lentriccia and McLaughlin (1990) ask, “How does any word make sense? It makes sense by being a part of a system of meanings, a set of contrasts and comparisons. No word has meaning in isolation but only insofar as it relates to and differs from other words in the language system” (pp. 85–86). As discussed earlier, part of the joint work of teacher educators, novices and experienced teachers who mentor novices is to understand
how the system of meanings—especially what is contrasted or compared or what is framed in certain ways—varies along with context and ideology. Usually, when we look closely at our use of language, we lay bare our biases and open ourselves up to other possible perspectives. In language we not only find metaphors amplifying meaning, but we find metaphors that push us to think about something familiar in new ways. Or, by juxtaposing unlikely images, we open up new ways of seeing, speaking, and thinking about them. In that sense, teacher educators, teacher candidates, and practicing teachers create openings to work together to uncover hidden meanings associated with their experiences so they can become more open to what else future experiences might hold, or what alternative explanations might be.

We are suggesting that when teacher educators and mentor teachers take on the responsibility to help novices become part of a community of practice, they are helping them learn a professional discourse. Linguist James Gee describes a “Discourse,” or a particular kind of community in which specialized cultural practices and uses of language along with other identifiable accoutrements of status and role are conferred on people who have undertaken specialized learning. These people can be identified as practitioners whose professional identity deeply penetrates their lives and relationships. For them, language is now related to culture and learning in new and particular ways. Gee writes,

Discourses are ways of being in the world, of forms of life which integrate words, acts, values, beliefs, attitudes, and social identities, as well as gestures, glances, body positions, and clothes. A Discourse is a sort of identity kit which comes complete with the appropriate costume and instructions on how to act, talk, and often write, so as to take on a particular social role that others will recognize.

(1996, p. 127)

When they investigate their own language use, professionals use language tentatively and judiciously, and they exercise the disposition to inquire into the hidden meanings behind their language. That means that they work with novices to avoid confusing naming (e.g. the “struggling reader”) with knowing how to enact practices that support all learners become successful readers. They take time to investigate meaning, pay attention to the rhetoric of teaching, what it is like, and what it reveals.

Creating new discourse communities

What are some examples of ways in which teacher educators can engage novices in this investigative work? Whatever the design, it must maintain complexity in teaching and learning and avoid simplification. As such, teacher educators work jointly with practicing teachers and teacher candidates to become weavers of experience. As weavers, there is the end in view of learning from experience, while still maintaining openness to experiencing and re-experiencing the ordinary in new ways. One design option is to partner with teacher study groups to co-create new discourse communities in which novices can participate. We offer three examples of educators’ efforts to stand outside familiar professional ways of thinking, speaking, and interacting. These examples address the figurative language—narrative and metaphorical—of our practice critically and imaginatively.

Descriptive review

The Philadelphia Teachers Learning Cooperative (TLC) found ways to investigate alternative meanings as they work to make sense of classroom life. They engage in oral
inquiries called “descriptive reviews” where teachers bring questions to the group that will help the teacher learn something new—about an approach to addressing a problem, a particular child, a discrepancy between a child’s work and behavior, and so on (Carini, 2000; Kanevsky, 1993). Presenting information to the group regarding five categories—children’s physical presence and gesture; disposition; relationships with children and adults; activities and interests; and modes of thinking and learning—teachers emphasize description and are open to alternative ideas. As Patricia Carini explained,

What does it mean to speak descriptively and provisionally? It means to set aside heavy judgmental language and diagnostic or other categorizing labels such as “hyperactive” or “learning disabled” or “developmentally delayed.” The chair [leading the discussion] explains that no child is always moving or invisible or pestering or whatever—not matter how much it seems that way to the harried or concerned parent or teacher. She suggests that phrases like “it seems to me” or “from my perspective” leave room for the child to be other than what any of us might think. The chair stresses that what is most important is to ground language used to describe the child in examples and illustrations so that the language is well rooted in observation.

(Carini, 2000, p. 14, emphasis in original)

In these ways, many perspectives on an issue or question are considered to make the issue more, not less, complex. Avoiding shorthand labels such as “hyper” or “disabled” or “delayed” permits teachers to focus on what the child can do, adding “... depth and dimension to the picture of the child” (Carini, 2000, p. 15) rather than speaking metaphorically about what the child cannot do relative to others.

Teacher study groups

In a second example, Anne Haas Dyson and her teacher colleagues gathered twice monthly during a full school year to explore the central question, “[W]hat difference does ‘difference’ make in our experience of the daily work of teaching?” (Dyson, with The San Francisco East Bay Teacher Study Group, 1997, p. 3). As the group explored this broad question in the context of teaching writing, they developed a more specific set of questions:

- What do we mean by “difference”?
- Who decides what or who is “different”?
- How and when do we experience “differences” in the course of our daily teaching? Are there particular dimensions of classroom life in which differences become salient in positive or negative problematic ways? What makes them “positive” or “problematic”?
- How do we make literacy curricula open to children’s diverse experiences and resources? How do we keep our activities flexible and our expectations forward looking?
- How do we help children themselves live in a world of differences?

(Dyson et al., 1997, pp. 3–4)

The group’s consideration of these questions from multiple angles yielded understandings of “horizontal differences among children (e.g. differences of language, cultural style, familial circumstance ... and vertical differences (i.e. differences where children
fall on the very narrow band of abilities and skills that mark even young children as ‘smart’ or ‘not,’ ‘ready’ or ‘not,’ ‘at risk’ or ‘not’) (p. 11). By thinking about learners as situated in classrooms and schools as institutions, these inquiring teachers probed ways in which language has the potential to shape what we see and understand about learners (or not) and to influence our curricular and pedagogical decisions.

**Professional networks**

In a third example, the Book Club Plus Network created in Michigan by Taffy Raphael and Susan Florio-Ruane linked teachers across urban, rural, and suburban districts in Michigan for inquiry-based professional development. The common project of the network was designing and researching ways to re-engage youngsters who, after several years of identification as struggling or slow readers, had disengaged from school-based literacy and adopted self-images as non-readers. The network was a collaborative. Running for five years, it involved teachers from many communities (K through middle school) with teacher educators and merged designs for educational improvement with their own professional growth. By designing, teaching, and assessing pilot curriculum, members of the network sustained and deepened relationships and created a field-tested conceptual framework for classroom literacy focused on the re-engagement of youngsters for whom reading has been a difficult, frustrating experience. They sustained the network by writing and publishing together, taking part in face-to-face discussions, visiting one another’s classrooms and homes, speaking on the telephone, communicating over the Internet, and coming together periodically for retreats (Florio-Ruane et al., 2004; Raphael et al., 2001).

Like the first two examples discussed above, these educators made language a focus of their inquiry and challenged the metaphors of “struggling” or “slow” readers as inadequate and inappropriate for effecting meaningful improvements in curriculum and instruction. They emphasized the nature of experiences children encounter in school and considered how those experiences make learning possible (or not), rather than labeling the children themselves with language that locates the problem within the individual child.

**Investigating culture, language and meaning**

Across these three examples, we see that variations in meaning of terms such as “struggle” or “difference” have profound implications for the choices beginning teachers make regarding teaching methods and materials and ways in which they organize their classrooms for learning. They have profound implications, as well, for which children are included or excluded in rich learning opportunities. For if the novice teacher concludes that the “struggling reader” must only read texts that simplify language and reduce struggle, then that reader may never have opportunities to work with rich, descriptive language that makes texts inherently artistic, poetic and interesting.

These educators are already engaged in important investigations into culture, language and meaning. As Cochran-Smith proposed years ago (1991), working alongside reform-minded teachers creates a rich learning context for novices and teacher educators alike because the joint work involves more than doing—it includes inquiry into current practices for the purpose of ongoing learning and educational reform.

**Using technological tools**

More recent technological innovations such as the use of multi-media video cases provide another avenue for investigating classroom life and meanings associated with it (e.g.
Kinser & Risko, 1998; Koehler et al., 1999; Lambdin et al., 1996; Lampert & Ball, 1998; Rosaen, 2002; Rosaen et al., 2004; Rosaen et al., 2002). Video cases can be created using a multi-media editor that lets users view, analyze, organize and comment on artifacts from classrooms (video, photographs, audio and a range of text files) to investigate the visible practice of teaching and raise questions about the associated thinking of teachers and students. These cases, designed with multiple paths to follow and a range of records of practice (Ball & Cohen, 1999) to investigate, are pedagogical tools that can help teacher candidates adopt an inquiring stance and flexible thinking about teaching and learning (Spiro & Jeng, 1990). Moreover, because video can be viewed repeatedly, there is the potential to slow down the rapid pace of classroom life and help novices learn to use concepts and theories to make sense of complex classroom interactions.

Close study of teaching and learning

For instance, teacher candidates can work in small groups and engage in multiple viewings of video clips and student work associated with a particular lesson. They can be encouraged to make explicit their assumptions about teaching and learning and compare and contrast their own interpretations with those of their peers. They can also be encouraged to ask questions (versus giving answers or explanations) about what they are seeing. Here is what one pair of students in Rosaen’s literacy methods class asked after viewing a guided reading lesson with James, an emergent reader, in a second grade classroom:

1. [We would like to know] what does the next day’s lesson look like to better help James [the focal student in the video] and other struggling readers to comprehend what [the book] they have looked at in this [video] clip?
2. How many other students are at James’s level and how does she [the teacher] help them? If there are multiple students at his level, why didn’t she take them into a small group and work on this text with them too?
3. Did it benefit James to work one-on-one with the teacher as opposed to working with a small group of students?
4. What was the rest of the class doing while [the teacher] was working solely with James?

(Student Work 11/9: Mary and Arlene)

Here we note that Mary and Arlene labeled James a “struggling reader,” which clues their instructor in to their use of the metaphor to interpret a student’s participation in the classroom. It also provides an opening to explore their interpretation further: Do they think James is “struggling” because he is reading at an emergent level while other second graders are reading chapter books? Or is this because they notice that James mentioned to the teacher that he read the same book in Kindergarten? What else did they notice during the lesson that indicates to them that he is “struggling”?

We also see that this pair of students is thinking about issues related to James’ membership in the learning community (e.g. how he is similar to or different from other readers and what sorts of social interaction might be beneficial for him). Additionally, they are questioning how the classroom is organized so the teacher can work one on one with a particular student. These questions indicate an awareness that there are many aspects teachers need to pay attention to during reading instruction—materials, grouping, student ability, classroom organization, and so on—that affect the learning of “struggling” readers.
Learning to notice across contexts

Learning to notice particular practices and connect them to broader understandings of meaningful instruction is complicated, especially during the rush of classroom activities and routines (Mason, 2002; Schultz, 2003; Sherin & van Es, 2002). The use of video cases in teacher education classes can blur the distinction between “the course” and “the field” and help prepare teacher candidates to perceive aspects of instruction in “real life” classrooms as well as to add to their developing repertoire of teaching practices, strategies and resources for teaching. Mary spent time in a third grade classroom and Arlene in a fourth grade setting as part of the methods course requirements. They noticed both similarities and differences in their beliefs and ideas about effective literacy instruction. When thinking about why these exist, they named several types of experiences that may have influenced their views:

Similarities exist due to the fact that we are both in the same section of [this course] and we are reading the same informational texts, discussing the same things, and even viewing the same [video] clips, as we frequently work together.

We feel that differences exist due to our varying experiences in our different classrooms. One may see something that works, while the other one may not experience it. Personal views may also come into play as we place emphasis on different things and feel that some things are more important than others.

(Student Work 11/16: Mary and Arlene)

Here it appears that Mary and Arlene see how a set of experiences—course readings and discussions, viewing video cases, and classroom participation—all contribute to their views. They attribute their areas of agreement to having shared experiences in the course, while areas of difference emerge from participating in different classroom settings for field experiences. They also assume their prior knowledge and beliefs interact with their current thinking. It is not clear whether they would agree with Lana’s comments, shared earlier, that “real world” (classroom) experience is the best kind, with course readings only contributing as a starting point for learning in the classroom.

Investigating curriculum, policies, and standards

Earlier we discussed ways in which teacher’s work and the metaphors embedded in it are both ideological and political. This suggests that “classroom life” is not all novices need to experience or think about. Other aspects of schooling such as curriculum materials, standards documents, and policies such as No Child Left Behind (2002) influence what teachers need to attend to in their work. They also affect teachers’ sense of agency regarding the type and amount of autonomy they have in the classroom (Pardo, 2006). Sometimes when we think of teachers’ needs across the career stages, we think of helping them first and foremost learn to manage and teach in the classroom and we tend to assume novices will leave other roles such as curriculum development work and taking on leadership roles to their more experienced colleagues. As Feiman-Nemser (2001) points out, teacher educators can design the progression of experiences novices are exposed to over time, centered on the central tasks of teaching. The curriculum can vary the level of responsibility, focus of attention and types of mentoring available and match beginning teachers’ developmental readiness and needs. She suggests a continuum that expands out from a focus on the classroom during the preservice years to include the community in the induction years and leadership roles in the broader profession in subsequent years.
However, a close look at ways in which the standards movement and pressures from policies such as NCLB and other high-stakes testing initiatives are currently impacting all teachers’ classroom practices (Anagnostopoulos, 2003; Copenhaver, 2001; Johnson, 2001; Johnson et al., 2003) suggests the need to rethink whether it is possible or even desirable to delay focusing novices’ attention on the communities in which learners in their field placement classrooms live and the larger issues that impinge on the work the teachers in field placement classrooms do. If novices are to perceive their experiences as events over which they have some control (versus being controlled by them), then they need to understand how they can and do take part in their own weaving of experience.

**Learning to question**

For instance, there are five skill areas included in No Child Left Behind (2002) legislation that are promoted as research based practices for literacy teaching and learning: phonemic awareness, phonics, vocabulary development, reading fluency, and reading comprehension. Yet the new Grade Level Content Expectations developed by the State of Michigan (released in the fall of 2004) include some additional categories that are deemed important to literacy teaching and learning: word study (as a part of vocabulary development), metacognition, critical standards and reading attitudes. There is ample research evidence that these areas are equally important to effective instruction as those targeted by NCLB (Palincsar & Brown, 1989; Pressley et al., 1987).

Novices who are taught to ask the question: *Who would have me believe what about this?* about any materials and requirements they confront as teachers would notice quickly that the additional areas of focus in the Michigan document move literacy teaching and learning beyond what might be considered “the basics” to engaging as well in higher level, critical thinking. Based on their analysis, novices might ask a follow-up question, *What does it mean to “leave no child behind” if all children are only getting “the basics”?* Even if they teach eventually in a “Reading First” School where funds are allocated to help states and local school districts offer effective reading instruction in grades K through 3 in very specific and prescribed ways, novice teachers must realize that they still have some instructional choices. They also must realize that they can justify their choices based on what is also expected by their own state and argue that these additional expectations are complementary to those found at the national level. In short, they can learn to view themselves as having some power over critical decisions regarding the learning opportunities available to children in their classrooms (Cochran-Smith & Lytle, 1999; Darling-Hammond, 1998; Firestone & Pennell, 1997). They can also learn to provide solid documentation regarding their students’ growth as readers, writers and thinkers (Bauer & Garcia, 2002).

**WHERE DOES UNDERSTANDING EXPERIENCE, METAPHOR AND CULTURE LEAD US?**

In a recent review of research on methods courses and field experiences, Clift and Brady (2005) concluded that there is a need in teacher education for rich, complex socio-cultural approaches to studying how beginners make sense of and interpret experiences. Our consideration of how metaphor brings together language, culture, activity and thought in ways that can both help and limit what beginners learn from experience suggests a similar need. As discussed in the introductory section of this
chapter, prior research on metaphors that reflect teachers’ conceptions of teaching and sense of self provides a foundation for further empirical work. We see a need to investigate ways in which beginning teachers’ explicit examination of metaphors that are pervasive in our culture and profession influence what they pay attention to as they experience various aspects of teacher preparation. For example, if teacher candidates have opportunities to investigate metaphorical language as part of study groups comprised of experienced teachers and teacher educators, what do these activities help novices notice and pay attention to? How does participation influence their understanding of their own responsibilities toward subject matter and learning? How do various metaphors shape how they name and frame instructional issues and what conceptual and practical tools do they use to address them? In what ways does looking at social, historical, political and ideological influences on language help them interpret experience? These are interesting questions worth investigating to understand more fully the metaphors by which beginners teach and how to help them consider alternative metaphors.

In this chapter we have also offered some alternative metaphors that could guide the design of teacher education. We suggested that thinking of the field as an ecological environment has the potential to foster interdependence and interaction among teacher candidates, teacher educators, and classroom teachers, rather than positioning learning experiences as taking place either “out there” in the field or “in here” on campus. We also suggested that thinking of teaching as weaving brings many layers into view, allowing for multi-dimensional investigation of discourse, classroom practice, curriculum, policy and standards. If these metaphors were used to design and redesign teacher education experiences, to what extent would the designs represent real change in how teacher education is carried out and evaluated? How would beginning teachers make sense of their experiences? To what extent do the experiences support novices in learning to think critically about ways in which metaphorical language shapes and structures experience? To what extent would they learn to choose metaphors that work in productive ways to guide their practice as opposed to working within tacit structures of which they are unaware? In offering new metaphors it is important to stand back from them and appraise them for their contributions to our work.

In the end, we need to learn more about how engaging in analysis of experience as the relationship among language, culture, activity and thought have the potential to transform teacher education to provide more powerful learning experiences. Because the metaphors that structure and guide our work as educators are rooted deeply in our culture and our profession and thus hold a great deal of power, it is important not only to understand them, but to make our own choices regarding their influence on what we do as educators.

NOTES

1 Partial support for the preparation of the chapter was provided by the Michigan State University Literacy Achievement Research Center (LARC). We acknowledge the encouragement we received from the late Dr. Michael Pressley, who served as the Director of LARC while we were writing this chapter. We also thank the students in our doctoral seminar, Using literacy to learn: curriculum and pedagogy, for many lively discussions that encouraged us to explore many of the ideas we developed this chapter. All ideas presented in this chapter are the sole responsibility of the authors.

The ideas and illustrative example are adapted from the essay, “How shall a thing be called?” by Roger Brown and Albert Gilman (1970).

Barton (1994) chose this metaphor as an alternative way to think about “literacy” because it introduced the idea of situated growth, the idea that growth happens in complex contexts.

Independent scholar

INTRODUCTION

The previous Handbook on Research in Teacher Education (Sikula, 1996) includes two chapters dealing with the “inner life” of the teacher: Virginia Richardson’s review of research on teacher attitudes and beliefs, and Kathy Carter and Walter Doyle’s review of research on personal narrative and life history. Richardson dismisses attitudes as weak indicators of teacher learning, while endorsing beliefs as important determinants of action. She defines beliefs as “psychologically held understandings, premises, or propositions about the world that are felt to be true,” (p. 103; Feiman-Nemser & Floden, 1986) and that stem from personal experience, experience with school, and experience with formal knowledge (Clandinin & Connelly, 1987; Elbaz, 1983). Given the tenacity of beliefs that spring from previous life history and student teaching, she concludes that teacher education is a relatively “weak intervention”. Although beliefs are clearly part and parcel of who one is as a teacher, Richardson does not directly address issues of identity and self.

Carter and Doyle take on the question of self and identity indirectly, through the lenses of personal narrative and life history research. Their research rests on the premise that “the process of learning to teach, the act of teaching and teachers’ experiences and choices are deeply personal matters inexorably linked to their identity and life story” (p. 120). Life history research highlights the social contexts that shape identity, while personal narrative emphasizes the fact that learning, including learning to teach, involves the construction of personal stories. Carter and Doyle conclude by stating that “from a biographical frame . . . becoming a teacher means (a) transforming an identity, (b) adapting personal understandings and ideals to institutional realities, and (c) deciding how to express one’s self in classroom activity” (p. 139). Clearly teachers are people who bring themselves into the classroom and the formation of their identities involves an interplay between external and internal forces.

This chapter does not refute these findings and perspectives. Rather, it shows how research over the past ten years has deepened and complicated our understanding of the role of self and identity in learning to teach, particularly by critical theorists (e.g. Britzman, 2003; Cochran-Smith, 2004; Giroux, 2005; Zembylas, 2003). Specifically, identity and identity formation have taken center stage, subsuming the categories of belief, attitude, life history, and personal narrative. In addition, research on the role of emotion in learning to teach and the development of teacher identity has gained a foothold. At the same time, the distinction and relationship between one’s self/ves and one’s
identity/ies remains murky. Finally, and importantly, there is a call from theorists for teachers to become aware of their identities and the political, historical, and social forces that shape them—in Britzman’s (1993) words, to “acknowledge the politics of identity.” In addition, theorists exhort teachers to assume agency, find their voice, and take the authority to shape their own professional paths and identities. Left largely unexplored by this literature, however, is the black box of how—how teachers should go about making the psychological shift from being authored by these forces to authoring their own stories, and how teacher educators might facilitate this process. This black box represents a psychological shift; it leads us to explore what developmental psychologists might contribute to the discussion. In particular, we take into account the view of constructive developmental psychologists who offer a potentially useful way to think about this shift. Many of the studies reviewed for this chapter were conceptual rather than empirical in nature. We hope that the introduction of a psychological frame will move the field of teacher education towards more empirical work in the development of self and identity in learning to teach.

This chapter is divided into four parts. We begin by exploring contemporary conceptions of identity and self, drawing on the teacher education and professional development literature. We follow this with a discussion of how constructive-developmentalists might illuminate our understanding of the development of self and identity. The third section looks at some promising programs from the past and present that support the development of teachers’ selves and identities. The final section concludes with a discussion of these model programs in light of constructive-developmental theory, and suggests directions for further research.

Definitions of self and identity

It is necessary to carve out of the vast literature on self and identity a workable set of definitions. For the purposes of this chapter, we have drawn our definitions from within the fields of teacher education and adult development.

The past ten years have seen a burgeoning of articles and books on teacher identity development. At the same time, studies of identity have cast doubt on the very concept of a “self,” which may explain why much less has been written about self as teacher. Still, confusion between the terms remains. As Beijaard et al. (2004) note in their review of research on teachers’ professional identity, “it remains unclear how exactly the concepts of ‘identity’ and ‘self’ are related” (p. 124). We first look at the larger field of identity formation, followed by the more elusive notion of self.

Contemporary conceptions of identity share four basic assumptions: (1) that identity is dependent upon and formed within multiple contexts which bring social, cultural, political, and historical forces to bear upon that formation; (2) that identity is formed in relationship with others and involves emotions; (3) that identity is shifting, unstable, and multiple; and, (4) that identity involves the construction and reconstruction of meaning through stories over time. Embedded in these assumptions is an implicit charge: that teachers should work towards an awareness of their identity and the contexts, relationships, and emotions that shape them, and (re)claim the authority of their own voice. This calls upon teachers to make a psychological shift in how they think about themselves as teachers. Contexts and relationships describe the external aspects of identity formation; and stories and emotions, the internal, meaning-making aspects. Awareness and voice represent the “contested” place where the normative demands of the external encounter the internal meaning making and desires of the teacher.
Identity as contextual

Identity is dependent upon the contexts in which we immerse ourselves: schools, teacher education programs, study groups, family, religious groups, political parties and so forth (Gee, 2001; Fitzgerald, 1993; Coldron & Smith, 1999; Beijaard et al., 2000, 2004; Britzman, 2003; Carter & Doyle, 1996; MacLure, 1993; Smagorinsky et al., 2004; Clandinin & Huber, 2005; Agee, 2004). Clandinin and Huber (2005) refer to context as “the landscapes past and present in which [a teacher] lives and works” (p. 4). Most definitions of identity take into consideration all four assumptions named above. A few, however, define identity solely as a matter of context. Fitzgerald (1993) writes that “... identity is defined as *the academic metaphor for self-in-context*” (italics in original, p. 3). Coldron & Smith (1999) speak of context as a matter of “space and location” and the identity of a teacher as “a matter of where, within the professional pertinent array of possibilities, a particular person is located” (p. 714). Contexts inevitably shape our notions of who we perceive ourselves to be and how others perceive us. We do not necessarily perceive contexts (which include ways of thinking and knowing) as much as we absorb them, often taking them for granted as what is “real.” Britzman (1993) for example, argues that contextual forces are normative and determined by those in authority who have a vested interest in the compliance of those under their authority. Within each context there exists a set of norms, and it is expected that these norms will be upheld by the participants within the given community. Lack of awareness of these norms and pressures to assimilate, keep teachers subject to contextual forces, robbing them of agency, creativity and voice.

James Gee (2001) provides the most elaborate view of these contextual forces, identifying four interrelated perspectives on identity: the nature perspective (N-identity, or those parts of who we are that have their source in nature rather than society, e.g. a tall person); the institutional perspective (I-identity, or those parts of who we are that have their source in institutional authority, e.g. a school teacher); the discourse perspective (D-identity, or those parts of who we are that have their source in the discourse or dialogue of other people, e.g. someone who is deemed by others to be a “charismatic” person); and the affinity perspective (A-identity, or those parts of who I am that have their source in a “distinctive set of practices,” e.g. a Red Sox fan). Each of these perspectives provides an “interpretive system underwriting the recognition of [one’s] identity” by others:

The *interpretive system* may be people’s historically and culturally different views of nature; it may be the norms, traditions and rules of institutions; it may be the discourse and dialogue of others; or it may be the working of affinity groups. What is important about identity is that almost any identity trait can be understood in terms of any of these different interpretive systems.

(italics in original, p. 108)

Gee uses the example of a label like “African American.” This label, viewed through different interpretive systems can be understood differently. Through the institutional lens of school, for example, being an “African American” child might be equated with being “at risk.” Alternatively, “African American” understood as an A-Identity, points to an affiliation with groups who share certain practices. “Here,” writes Gee, “people do not see themselves as African American primarily because of ‘blood’ (an N-Identity), because of an institutional category (an I-Identity), or because others respond to them, for better or worse, in certain distinctive ways (a D-Identity)” (p. 108). He suggests that
in this case, a “Black” person could claim that they have chosen not to be African American and a “White” person could claim to be African American. In this way identities are a matter of negotiation with others. “Thus,” writes Gee, “people can accept, contest, and negotiate identities in terms of whether they will be seen primarily (or in some foregrounded way) as N-, I-, D-, or A-Identities. What is at issue, though, is always how and by whom a particular identity is to be recognized” (italics in original, p. 109). And this points to the second assumption of identity: that it is relational, and hence, also emotional.

Identity as relational and emotional

Within multiple contexts one forms multiple relationships, and brings forth multiple aspects of oneself. Gee (2001) points out that relationship cuts across all four of his perspectives on identity. Relationship is essential to identity primarily because to have an identity one must be recognized as a particular “kind of person” by others.

Smagorinsky et al. (2004), in their study of identity formation among new teachers, conclude that identity is co-constructed “through engagement with others in cultural practice” (p. 21). Samuel and Stephens (2000) observe multiple layers of relationship and negotiation in their work with black South African teachers, where teachers “walk a tightrope in both developing a personal teacher identity which sits comfortably with their own sense of self,” and satisfying state requirements, while at the same time embodying reform by being “the impetus for change,” including acting as critics to the very teachers who are assigned to be their mentors (p. 478). Complicated identities, indeed!

That the complex relationships between teacher, students, colleagues, mentor, school, community and state would provoke emotion is no surprise. Emotions have been taken up increasingly as a critical aspect of identity formation (Britzman, 1993; Hargreaves, 2001; Zembylas, 2002, 2003; Winograd, 2003). “Feelings,” Britzman asserts, “are made in social relationships.” In particular, she cites the friction created between institutional structures and expectations of how teachers should behave and feel and the actual “structure of feelings” that teachers already hold because of who they are, and “the lives they live” (p. 252).

In his discussion of “emotional geographies,” Hargreaves (2001) also takes up the ways in which teachers’ emotions are “embedded in the conditions and interactions of their work.” Emotional geographies consist of “the spatial and experiential patterns of closeness and/or distance in human interactions and relationships that help create, configure and color the feelings and emotions [he does not distinguish between the two] we experience about ourselves, our world and each other” (p. 1061). In other words, teachers’ emotions are shaped by the conditions of their work (for example, high-stakes tests) and are then manifest in their interactions with students, parents, administrators and others. In his interviews of 53 elementary and secondary Canadian school-teachers, Hargreaves identifies five different emotional geographies: socio-cultural, moral, professional, political, and physical. Each involves either a closeness or a distance—distance driving wedges between people, and closeness forming bonds. For example, a socio-cultural distance might exist between a white middle-class teacher and her less-economically secure students. Moral distance exists when “teachers feel their purposes are being threatened or have been lost” by those around them (p. 1067), for example, when a school’s priority is high test scores rather than student learning. Hargreaves advocates a deeper understanding of these geographies as key to making the relationships of school work, and, by implication, making teacher identity less fractured.

Zembylas (2002, 2004) echoes Hargreaves’ notion of distance when he speaks of the
“emotional labor” in which teachers must engage in an effort to conform to what is deemed appropriate within schools (the “emotional rules” of school): “teacher identity and emotion discourses are formed within specific school political arrangements, in relation to certain expectations and requirements, ones that presume a teacher should conform to particular emotional rules (e.g. teachers should leave their emotions ‘outside’ the classroom . . .)” (p. 226). Winograd (2003), an education professor who returned to elementary school teaching for a year, brought the theories of emotion outlined above to bear on his experience back in the classroom. During his year as a teacher, Winograd faced challenges, particularly in classroom management, that caused him to question his own identity as an effective educator. He found himself caught in a cycle of self-blame, often experienced by new teachers, where the school culture made it easy “to conclude that failure or struggle is [teachers’] fault alone and that structural conditions are less influential than the individual’s own failings” (p. 1669). Feelings of anger, for example, were experienced as bad in the face of a culture that see teachers as restrained, gentle, and nurturing.

Identity as shifting and multiple

As implied above, when teachers’ identities are shaped, at least in part, by the external forces of context and relationships, identity necessarily becomes a multiple and shifting affair, in process and changeable. As Gee writes, “The ‘kind of person’ one is recognized as ‘being,’ at a given time and place, can change from moment to moment in the interaction, can change from context to context, and of course, can be ambiguous or unstable” (p. 99). Identity is therefore not only shifting but also multiple. Beijaard et al. (2004) in their review of the research on teachers’ professional identity, note that because identity is relational, it is also shifting, and constantly in the process of becoming.

[Identity] is not a fixed attribute of a person, but a relational phenomenon. Identity development occurs in an intersubjective field and can be best characterized as an ongoing process, a process of interpreting oneself as a certain kind of person and being recognized as such in a given context. In this context then, identity can also be seen as an answer to the recurrent question: “Who am I at this moment?” (p. 108)

What is important here is that identity: (1) is always “in the making,” rather than stable, (2) shifts according to context and relationships, and (3) is therefore varied and multiple.

Identity as storied

Thus far, identities appear to be like a deck of cards spread out on a tabletop; any one might be turned up at any time, depending upon the who, what, and where of circumstance. Continuity and coherence suggested by the terms identity formation or identity development feel elusive. There is a need for making sense—an internal arrangement and control of things so that the shifting, multiple, constructed, contradictory, confusing, cubistic thing called identity becomes useful. The most widely embraced way of making sense is through the practice of narrative, or the telling of our stories. “Nowadays,” as Beijaard et al. (2000) note, “identity formation is conceived as an ongoing process that involves the interpretation and reinterpretation of experiences as one lives through them” (Kerby, 1991, as cited in Beijaard et al., 2000). The foremost proponents of this point of view are Michael Connelly and D. Jean Clandinin (1986, 1995, 1999, 2000). Based on
Spence’s (1984) notion of the narrative construction of the self (side-stepping for a moment any definition of self), Connelly and Clandinin understand a teacher’s identity as “a unique embodiment of his/her stories to live by, stories shaped by the landscapes past and present in which s/he lives and works . . .” (as cited in Clandinin & Huber, p. 4). Sfard and Prusak (2005), equate identity with the construction of stories. They parse the process further by articulating a tripartite picture of identity: first-person identities (stories a person tells himself about himself), second person identities (stories told about oneself to oneself by a second person), and third person identities (stories told about oneself by a second person to a third person). Identity, then, is both interpreted and constructed through the stories that one tells oneself and that others tell. These stories change over time, across contexts, and depend upon relationship.

**Awareness and voice**

The four assumptions described above address the nature of identity. Awareness and voice, however, point to what theorists believe teachers do in light of those assumptions. Identities form and develop as a result of interactions, but not necessarily as a result of awareness. Theorists, however, call for teachers to develop an awareness of the normative contextual and relational forces that shape their identities. They exhort new and experienced teachers alike to “resist” these normative forces, forces which are “overburdened with the meanings of others,” and author their own identities according to their own “deep convictions, investments, and desires” (Britzman, 1993, p. 33). Voice, Britzman contends, struggles to emerge from the confluence of forces that compete for a teacher’s allegiance: the schools and universities in which she works and learns, her past experiences and identities as a learner, and her desires and images of herself as a teacher. Finding one’s voice implies not having others (researchers, school boards, text books) speak for us, not being silenced by authorities or normative notions of who teachers should be, in effect, to be the author of one’s identity.

Like Britzman, Zembylas (2002, 2004) advocates developing an awareness of and resistance to the normative forces of school, and encourages teachers to “try to think differently, to ask themselves not only how discourses on emotions and the various norms in their school have shielded them from their desires, but also how it [normative discourse] has installed those desires as what they presume themselves to be” (p. 229). Awareness of the emotions (as manifested in the body—e.g. facial gesture, the eyes, the gut) that are triggered within the context of school, and the forces that bring them about, he argues, prepares the road to voice, agency and self-transformation, especially when done in the company of others.

Winograd (2003), reflecting on his year as an elementary school teacher, advocates teachers forging relationships with other teachers in order to “study, share, and use their emotions for social change,” by holding up for critique the kind of “emotional rules” that schools can impose (p. 1670).

What it takes to move from being “authored by” to “authoring” oneself is not, however, addressed in detail in the literature. It also begs the question of self in contrast to identity. If one’s identities are to be “self-authored,” then who is the “self” doing the authoring? It is at this juncture that discussion of an aware, active self is useful.

**Self as maker of meaning and agent**

The literature on the self reviewed here (Dewey, 1938; Kegan, 1983; Gee, 2001; Nias, 1989; Palmer, 1998) assumes that there is more to a self than simply an array of shifting
identities. There is a notion of continuity and coherence that signals a self, even as there are discontinuities, shifts, and crises that signal an *evolving* self. In effect, the self can be seen as the meaning maker, or the teller of stories. If our identities are stories, then our selves might be the storytellers. As a bridge to this notion of self, we again turn to Gee who, in his discussion of identities, speaks briefly of a “core identity.” One’s “core identity,” he writes, is different from one’s “identities” which are multiple and connected “not to [one’s] ‘internal states’ but to [one’s] performances in society.” One’s core identity, in contrast, is something “that holds more uniformly, for ourselves and others, across contexts” (p. 99).

John Dewey references the importance of such coherence across contexts. He writes that when coherence is lacking, a person, in a sense, “cracks up”:

> A divided world, a world whose parts and aspects do not hang together [for a person], is at once a sign and a cause of a divided personality. When the splitting-up reaches a certain point we call the person insane. A fully integrated personality . . . exists only when successive experiences are integrated with one another.

(p. 44)

The integration, he argues, is a matter of the meaning that is made of experience through reflection. Similarly, Polkinghorne (as cited in Bruner, 1990) spoke of the self as “a configuring of personal events into an historical unity” (p. 116).

Jennifer Nias (1989), citing Foulkes (1975) and Mead (1934) distinguishes between a substantial self (I) and situational selves (me). The substantial self, formed primarily at, and even before, birth and in the early years, is embodied in values shaped by family and one’s immediate culture. The substantial self remains relatively impervious to change. One’s situational selves can be thought of here as one’s identities. Our situational selves, she argues, “incorporate those beliefs, values, and attitudes which we feel to be most self-defining” (p. 163). The I-substantial self is subject and the me-situational self, object. The former is not knowable except as it becomes object. Reflection is the tool the self uses to know one’s situational selves, which change over time. What Nias and others call the self or the private self, Britzman refers to as “being.” It is both conscious and unconscious and therefore can really only “hint at itself”:

> In my view, the self and identity are maybe two sides of the same coin. I have come to believe that there is an unknowable core, something that resists sociality, and can only hint at itself. I would not locate this core in identity, which I tend to think of as the social clothing plus desire for recognition. Within this clash or conflict, there is something called the private self, which I would call “being.” Here is where I would locate interiority that may fuel the need for identity but in and of itself the self is not coextensive with identity, or another way of saying this is the self is not identical to itself as the philosophers might say.

(Personal communication, August 2005)

Parker Palmer (1998), educator and author of the popular book, *The Courage to Teach*, distinguishes between identity and integrity in defining the self. Identity, he says, is the “evolving nexus where all the forces that constitute life converge in the mystery of self . . . In the midst of that complex field, identity is a moving intersection of the inner and outer forces that make me who I am, converging in the irreducible mystery of being human” (p. 13). Integrity differs from identity in that it suggests a conscious weaving together of some kind of meaning out of the experiences that comprise one’s identity. It is
“whatever wholeness I am able to find within that nexus [of identity] as its vectors form and re-form the pattern of my life. Integrity requires that I discern what is integral to my selfhood, what fits and what does not—and that I choose life-giving ways of relating to the forces that converge within me” (p. 13).

Psychologist Robert Kegan (1982), writing from a constructive-developmental perspective, holds that at every stage of development, the “self” coheres in an organized system of meaning and meaning making. It coheres differently at each stage (something which we explore more extensively below), but there is a balance in place that allows one to be. “There is presumed to be a basic unity to personality, a unity best understood as a process rather than an entity. This process, according to [Carl] Rogers’ conception, gives rise to the ‘self,’ the meaning-making system with which the process gets identified” (p. 5).

Self, then, might be thought of as the meaning maker and identity as the meaning made, even as the self and identity evolve and transform over time. The self in its completeness, however, remains unknowable. It is, as Palmer says, an elusive reality “that can be caught only out of the corner of the eye.” Still, despite the inevitable discontinuities and change and the intangible nature of self, there is a belief that there exists over time a “Self” that is recognizable and a coherence that allows one to move in the world with a certain confidence. For the purposes of this discussion, then, self will subsume identities and will be understood as an evolving yet coherent being, that consciously and unconsciously constructs and is constructed, reconstructs and is reconstructed, in interaction with the cultural contexts, institutions, and people with which the self lives, learns, and functions.

Looking at self and identity formation through a constructive-developmental lens

Because Kegan (1982, 1994) clearly articulates a process of growth and change as well as distinct developmental stages in adulthood, his theoretical framework is a useful lens with which to consider the hidden developmental demands that are at work in the literature on teacher identity. How a teacher makes sense of her teacher identity evolves out of the developmental capacities of the self. That is, lying underneath the four basic assumptions about teacher identity is the question: how? How does the teacher make sense of social, cultural, political, and historical forces? How does she make sense of her relationships with others? How does she construct and reconstruct meaning through stories? It is in the answer to this question, how, that we are able to identify qualitatively different ways that teachers make sense of their experiences; these differences reflect the differing developmental capacities of teachers’ selves, and therefore, color and shape how they make sense of their identities.

The different ways in which teachers might answer these questions are reflected in Table 40.1 below.

Kegan’s conception of self suggests that the way the teacher self makes sense of his/her experience is, in fact, different at different developmental stages, and that it evolves over time. These differences reflect teachers’ varying capacities to take a perspective on their experiencing (i.e. their developmental structure) as distinct from differences in the content of their teaching (i.e. their discipline, teaching strategies, area of discipline), teacher education experiences (the philosophy of the program, the expectations of the program), or identity (i.e. sex, socio-economic status, religion, political position, etc.). Developmental structure or stage reveals the specific ways in which individuals make sense out of experiences that are seemingly similar.

</table>
Kegan delineates five developmental stages; however, for the purposes of this discussion, we will only address stages two through four. At Kegan’s stage 2, or the Imperial Balance (Kegan, 1982, 1994) one has the capacity to take the role of another person, and to view oneself as distinct from the other. At this point in development, there is an emergence of self-concept, a consistent notion of me, an enduring set of dispositions (Kegan, 1982, p. 89). While the success of this developmental stage is that one is in a “project for oneself” (p. 89), one is not yet able to coordinate the perspective of another with one’s own perspective and one understands the world in highly concrete terms. The teacher at this developmental stage is likely to conceive of the teacher role as a means to fulfilling her own purposes (or her own project in some way—as a fulfillment of herself [Scott, 1999]). Because she does not yet have a perspective on her own needs, desires or interests, she is not able to articulate them. Her self is made up of these needs, desires, and interests. As a result, any attempt to engage in self-reflection would be characterized by a very concrete, black and white analysis.

At Kegan’s stage 3, or the Interpersonal Balance (also known as the “socialized self”), the self “embodies a plurality of voices” (1982, p. 96). The teacher self at this developmental stage is subject to the demands of her surround; as such, the notion of multiple identities, may be a developmental notion. The self is authored by the context of relationship. Teachers at this developmental stage are likely to enact the teacher role that is ascribed by the culture generally, or the most significant contexts of which the teachers are a part (i.e. teacher education program, school context). They take their cues from the cultural surround and seek approval and feedback from their surround as a measure of how well they are doing (Scott, 1999). Thus, their measurement of success or well-being is defined according to external standards rather than according to internal standards defined by them. Although they are able to engage in self-reflection, the nature of their reflection is focused on the way they view their teaching in relationship to the expectations or demands that are defined by the “authorities”—those who author or
define their experiences for them (i.e. the institution of school, teacher education programs).

At Kegan’s stage 4, or the Institutional Balance (also known as the “self-authoring self”), the self moves from being defined by external sources to being defined internally. The self is its own system with a clearly defined set of values, a clear philosophy. One is no longer pushed and pulled by the needs, wants, or expectations of others. Rather, the self is able to take a perspective on information, evaluate it, and then decide how to act upon it. Teacher identity at this stage is defined internally; it is no longer subject to the demands/expectations of the cultural surround. Teachers at this stage are able to take a perspective on their identities; it is at this developmental stage that they are able to evaluate the ways in which the different aspects of their selves (i.e. their identities: socio-economic class, race, culture, history, etc.) are borne out in their teaching and in their relationships with their students, and engage in a critique of their teaching according to their own standards rather than by the standards of others.

Kegan’s view of an evolving self sheds new light on the literature on teacher identity. It helps to illuminate the varying capacities of teachers to respond to the calls that they: (1) become aware of their identities and the political, historical, and social forces that shape them; (2) assume agency, find their voice, and take the authority to shape their own professional paths and identities. Clearly, these calls assume that these teachers are self-authoring in their developmental orientation; in fact, this claim may put teachers at risk for being “in over their heads” (Kegan, 1994). Nevertheless, what is revealed is that there is a hidden developmental expectation that teachers do, in fact, possess these developmental capacities. Returning to the question that we posed at the beginning of this chapter: how should teachers go about making the psychological shift from being authored by these forces to authoring their own stories and how should teacher educators facilitate this process?

The way that teachers construct their relationship to their teacher role does not by itself indicate how teachers will fare in teacher education, nor how they will fare as beginning teachers. Rather, there is an interaction between how teachers make sense of their role, the norms/values of the culture in which they are situated (the culture of the graduate school curriculum, the culture of the school in which they are teaching), and the available supports. To be at a higher developmental stage could be an asset or a risk. Likewise, to be at a lower developmental stage could be an asset or a risk. To determine whether developmental capacity, or the way that a teacher makes sense of his/her experience is an asset or a risk, consideration must be given to the developmental demands of the context (teacher education program, the culture of school) and the available supports (Berger, 2002; Daloz, 1999; Drago-Severson, 2004; Kegan, 1982, 1994; Scott, 1999). In this regard, Kegan states,

If I were to stand on one leg, like Hillel, and summarize my readings of centuries of wise reflection on what is required of an environment for it to facilitate the growth of its members, I would say this: people grow best where they continuously experience an ingenious blend of support and challenge; the rest is commentary. Environments that are weighed too heavily in the direction of challenge without adequate support are toxic; they promote defensiveness and constriction. Those weighed too heavily
toward support without adequate challenge are ultimately boring; they promote
devitalization. Both kinds of imbalance lead to withdrawal or dissociation from the
context. In contrast, the balance of support and challenge lead to vital engagement.
(1994, p. 42)

Daloz (1999) illustrates this relationship between support and challenge to engagement
or disengagement in the following diagram:

![Daloz's Matrix of Support and Change](image)

**Figure 40.1** Daloz’s matrix of support and change.

Daloz states that the function of support is “to affirm the validity of one’s senses” and the
function of challenge is to “open a gap between students and environment, a gap that
creates tension in the student—calling out for closure” (p. 213). Like Kegan, he suggests
that a balance of support and challenge is what will best promote the growth or evolution
of the student’s or the teacher’s self. Both Kegan (1994) and Daloz (1999), however,
cautions that what one person (teacher) may experience as support may be experienced as
challenge by another, and vice versa. Thus, from a developmental perspective, an effective
teacher education program must take into account the goodness of fit between how its
students are making sense (developmental structure) and the developmental demands of
the curriculum. If the program assumes that all teachers make sense in one way—that
they all have the same developmental perspective—some students will likely meet with
success and others will not. However, their success or failure will have as much to do with
the developmental demands of the program, as with the effort, motivation, or determina-
tion of the students. In other words, a student could be very motivated to participate in
the program, but because there is a mismatch between her way of knowing (developmental
stage), and the developmental demands of the environment, she could become
disengaged. Without attention given to the goodness of fit between the developmental
demands of teacher education programs, and the developmental capacities of prospective
teachers, we will fail to understand why teacher education programs are successful in
promoting/supporting the development of the teacher self for some students, while they
are not for others (Berger, 2002).
TEACHER EDUCATION PROGRAMS THAT EDUCATE SELF AND IDENTITY

The programs outlined below, both historical and current, offer examples of ways in which teachers can be both challenged to become aware of the ways in which their identities are shaped by their contexts and relationships, and supported in reflection upon those forces in order to become more self-determining. We look at four historical teacher education programs that explicitly educated the personal/critical/social self, and current efforts to educate awareness of self and identity.

A short history of teacher education and the personal/critical/social self

In Feiman-Nemser’s (1990) outline of conceptual orientations in teacher education, the personal and critical/social orientations (which are most closely aligned with work on self and identity) are included along with the academic, practical, and technological orientations. Where the practical and technical orientations emphasize “additive” knowledge and skills, the personal and critical/social orientations demand awareness and a transformation of the “self,” (of the meanings one makes and the internal and external forces that shape those meanings), and encourage teachers to take action based on their learning. The programs described below affirm the unique humanity of the teacher, but also ask new and prospective teachers to take a critical look at themselves and the privileges and inequities of their own and their students’ lives. In this section we describe how four early, alternative teacher education programs, the teacher center movement and several contemporary efforts sought to support teachers in the development of self-awareness and voice, or to make that psychological shift from being authored by external forces (e.g. historical, political, social) to authoring their own teacher identities.

Leading teacher education programs regarded the growth of teachers as inseparable from the growth of persons, in both humanistic and critical/social terms. Among the teacher education programs embodying this stance were Bank Street College, (started in 1930 under Lucy Sprague Mitchell), The Prospect School Teacher Education Program (1968–1990, initially under the direction of Patricia Carini), New College (1932–1939) of Columbia Teachers College, and the Putney Graduate School of Teacher Education (1950–1965, under the direction of Morris R. Mitchell). These private programs operated with small numbers of students. Variously influenced by the thinking of John Dewey, Maurice Merleau-Ponty, Alfred North Whitehead, and Theodore Brameld, they had well-articulated philosophies and values regarding teaching and learning, which included the importance of self-knowledge. One might say they had strong programmatic identities. They valued close observation of and inquiry into children’s learning as well as the world around them and recognized the role that the teacher’s perceptions and preconceptions played in learning to see children and their learning. As Morris Mitchell wrote, “A teacher teaches who he is.” In other words, since a teacher teaches from herself, self-awareness is an ethical necessity. It is also the source of her power. These programs also emphasized the teachers’ role as citizen and educator of citizens in a democracy. As Jaime Grinberg (2002) noted of Bank Street, it “assume[d] a need for teachers’ own social perspectives to be explored and the need for teachers to engage actively as participants in social and civic responsibilities” (p. 1430).
Teacher education programs

These programs shared several characteristics which influenced the ways in which they challenged new teachers to become aware of and to interrogate their past experiences, their beliefs and assumptions about school, schooling, and the contexts within which they lived and worked, while offering them the necessary support to make a transition from old perspectives to new ones. First, each program had a clearly defined mission that saw education as a key to a democratic society. They linked teachers’ personal and professional identities to the larger societal causes that reached beyond the circumscribed world of the classroom or their personal lives (e.g. social justice, racial equality). Second, as progressive programs, their approach to learning and teaching was experiential and necessarily included both experience and reflection. The experiences included one’s own past, one’s existing perspectives on learning, teaching, and school, and the decisions made in one’s teaching present. As such, reflection on experience was meant to lead to self-awareness.

Mission

All these programs, but most clearly the Putney Graduate School and New College of Columbia, saw their purpose as the building of a better society. The development of the person was not their end goal. Rather such development was in service of the larger goals of children’s own learning and development and eventual transformation of society. New College, which suffered an early demise (Teachers College News, 2001), was an experimental undergraduate, four-year teacher education program within Columbia Teachers College. It combined a liberal arts curriculum with a focus on social problems which future teachers were expected to address. Students spent their time between New York City and the New College Community, a student-run farm in Ashville, North Carolina. They also studied abroad for at least a summer in an effort to experience peoples and cultures different from their own.

Once a faculty member at New College, Morris Mitchell, who later directed the Putney Graduate School of Teacher Education, wrote that education should “become a dynamic for peace” in the world. This was accomplished, he believed, by immersing students in a variety of experiences that awakened them to problems of poverty, war, and racial injustice. This usually involved a long trip, or Study Tour, South, often to sites of what Mitchell termed, “quiet revolution,” where people involved in the Civil Rights movement and sustainable land development were working.

Bank Street and Prospect also adhered to purposes beyond the bounds of school and test results, and saw education as linked to principles of democracy. Bank Street took teachers into the streets of New York City to explore the workings of the city and on Long Trips to explore the larger issues of the nation. As Grinberg (2002) notes, “Bank Street . . . emphasized that teachers ought to engage in systematic investigation of communities and social relations as an integral part of learning to teach . . . [and that] issues of social justice not only have to be studied but also must be experienced, lived” (p. 1431).

While Prospect’s mission was less overtly attuned to broad political and social issues, it was grounded in questions that mattered. What makes us human? How can teaching bring forth and nurture the humanity of a child? What resources and activities manifest the complexity and humanness of the child? How are universal human themes reflected in the disciplines? These commitments lifted the sense of oneself above the particular. Yet deep knowledge of the particulars of experience (as revealed through reflection) grounded teachers’ (and students’) investigations (Rodgers, in press).

Experiential learning, reflection, and self-awareness

In each program, awareness of oneself was developed through recollection of past experience, interaction with the “stuff” of the world, and observation of children’s interactions. At Prospect and Bank Street, especially, teacher-students were asked to recall their own experiences as children, to play with blocks, clay, and wax, for example, and to closely observe children on a daily basis. They were asked to both describe their own and others’ experiences with awareness of the potential interference of pre-conceptions, and to reflect on the meaning of what they had observed (either from childhood or in the present). Carini (like Dewey) believed that a human being is knowable in his or her interactions with the world. It is therefore important to observe those interactions closely and carefully. In the observing of the other, one gains knowledge of one’s own self. Carini (1979) writes:

When the perception of the other person is based on direct access through the expressiveness of the body in its engagement with things-in-the-world, there is an assumption of co-extensive beings united through the shared world setting. From that assumption, it can be derived that self-knowledge and knowledge of others are achieved reciprocally and intersubjectively.

(p. 29)

At Bank Street, student teachers “engaged in treating their own learning experiences as a subject matter of study” (Grinberg, 2002, p. 1429). Bank Street sought “to promote the development of personal powers . . . to treat the student-teachers as we should treat children—only on a higher level” (Lucy Sprague Mitchell, 1931, as quoted in Grinberg, 2002, p. 1430). As Grinberg (2002) explains,

the purpose was to further the connections with children’s learning. After the student teachers learned the content, understood relationships [through reflection], and had a powerful personal experience that helped them construct personal meanings, they had to plan the environment to provide their own students in their particular classrooms with concrete experiences that would further learning.

(p. 1435)

New College and Putney also relied on experience and reflection as the vehicles of learning. In each case, students would come up against themselves and the assumptions and prejudices that resulted from their own particular histories. Putney students began the year by writing an autobiography that was read aloud to their fellow students. “Writing the autobiography was one way of sorting through what brought students to the Graduate School and getting at what was termed ‘felt needs.’ . . . Once uncovered, these needs or desires served as the impetus for study” (Rodgers, 1998, p. 102). To a large extent, though not exclusively, students at Putney determined their own course of study. Throughout their time in the program, they kept reflective journals of their experiences, met regularly with director, Morris Mitchell, and with his guidance, structured and restructured their course of study, as well as their stories of their experiences—in short, their identities.

Each of these progressive teacher education programs relied heavily upon advising systems that allowed students to explore in depth their personal experiences as both learners and teachers, one-on-one and in small groups with a faculty advisor. In large part, these sessions were forums for reflection, which, coupled with their experiences, provided a bridge that carried teachers from a place of being authored by their past,
(e.g. traditional school systems, a racist society, or a world of privilege) to one where they might question these systems and assumptions and begin to construct a learning environment that resonated with their own emerging voice. For the most part, these private programs sent teachers into private schools where teachers’ emerging voice resonated with the song of the institution they had chosen, and which had chosen them.

**Contemporary approaches and programs**

Echoing these older programs contemporary progressive programs (e.g. Cook-Sather, in press; Smulyan, 2004; Elbaz-Luwisch, 2002; Korthagen and Vasalos, 2005; Featherstone, 1993; Abu El-Haj, 2003; Palmer, 1998; Intrator, 2002) advocate creating time and space for reflection, creating communities of trust and making sense of experience through stories. They, too, ask teachers to confront and speak back to the external forces that shape and limit who and what a teacher is, that is, using the language of today, to become aware of one’s various identities and to cultivate a teaching self that is self-authored.

As we have already mentioned, most of the studies reviewed for this chapter were theoretical in nature, and either speculated about practices that might support teachers’ identity formation, contained first person teacher reports on identity transformations, or exhorted teacher education and professional development programs to address teacher identity. Empirical studies are relatively scarce. Of the more than 40 articles and books reviewed, only about a third reported on courses or programs that worked explicitly with teachers’ identity formation. Many of those were self-reports. Of these, three reported on isolated courses and seven described substantial programs. Nonetheless, promising contemporary programmatic efforts rely on familiar tools, techniques, and structures like journals and autobiographies, teacher study groups and book groups, action research and collaborative research. In addition, some initiatives embed these strategies in a larger mission and set of beliefs that may potentially provide the kind of developmental bridge of challenge and support of which Kegan and Daloz speak. However, it is important to note that none of them addresses the fact that developmentally, not all new teachers may be ready to cross that bridge. A description of a selection of these efforts follows.

One useful concept that resonates with Kegan’s idea of a developmental bridge, is the idea of “liminal” time and space. Alison Cook-Sather (2005), drawing on the work of anthropologist Victor Turner, describes liminality as “outside of standard, hierarchical structures of institutional relationship, power, and action,” and between one way of being and another, new way (p. 7). In Cook-Sather’s program, pre-service teachers work with experienced teacher partners in a liminal time and space created by e-mail. The experienced teachers are not students’ cooperating teachers but participate actively in the design and delivery of the teacher education program. The outside-of-time-and-space aspect of the e-mail environment provides an opportunity “both for initial processing and then dialogue” that allows new teachers to “re-imagine” and “transform” themselves from students to teachers in an unpressured environment, hearing their own voices against the backdrop of the normative voices they hear so loudly in the context of school.

Smulyan (2004), in her ten-year study of female graduates of an elite liberal arts college, speaks of the college experience in general as a time and space where her students were encouraged by the institution as a whole to redefine what it means to be a “successful” woman. Students came to this college with the externally crafted notion that success meant a lucrative career as a doctor, lawyer, or engineer. Through the course of their education, their concept of success changed to a more internally defined set of criteria. This happened through a process of reflection on “social and internalized frameworks,”
and included a reframing of teaching not merely as a helping, woman’s profession, but as a means to “change a society that they see as inequitable and unjust” (p. 535). Smulyan attributed this shift in part to the knowledge, skills, and language the college provided to describe and explain students’ gendered experiences as teachers.

Another example comes from Elbaz-Luwisch’s (2002) work with “storying the teacher-self in writing workshops.” Elbaz-Luwisch sees autobiography as a place, again, in the liminal space between identity as student and that as teacher, for the persuasive inner voice (the self?) to counter authoritative social discourse (Britzman, 2005, personal communication). Through describing, storying, and questioning in small groups of trusted colleagues, the self reframes experience and begins to assume the authority of his or her identity instead of ceding it to external forces. Writing, Elbaz-Luwisch says, acts as mid-wife to the teacher’s own “becoming.”

While several programs refer to reflection as a necessary tool for making meaning, questioning external authorities, and constructing identities, many left the actual process of reflection undefined. A few, however, were specific in describing the reflective processes to which they refer. Elbaz-Luwisch (2002), for example, outlines a clear process of description, storying, and questioning, a process she calls “restorying.”

Korthagen and Vasalos (2005) describe a Dutch teacher education program that utilizes “core reflection.” Core reflection aims at an awareness of the “core of one’s personality,” namely, identity (the kind of teacher one wants to be) and mission (why a person teaches, their calling) and the emotions that accompany such work. The teacher, in partnership with an empathetic and skilled supervisor, goes through an iterative process of action, looking back at action, developing awareness of the mission and identity played out in—or missing from—that action, and devising plans for alternative actions. In the process, the teacher becomes aware of the “less rational” sources of behavior: one’s self-concept, fears, desires, and “deepest motives for becoming a teacher.” The authors argue that such awareness can effect change in teacher behavior, and even in the school.

The reflective practices of groups like the Philadelphia Teachers Learning Cooperative (PTLC) (Featherstone, 1998; El-Haj, 2003), affiliated with the Prospect Center for Education and Research in North Bennington, Vermont and the Teacher Knowledge Project of the School for International Training in Brattleboro, Vermont are also clearly spelled out. The PTLC has met as a group of new and experienced teachers once a week for over 25 years. It (along with several other similar groups across the country) continues to follow the descriptive processes developed at the Prospect School. These include descriptive reviews of children, descriptions of student work and descriptions of practice. The objective of these processes is to carefully gather evidence that allows a teacher to see a child and his or her work without resorting to labels, or jumping to judgments based on unexamined assumptions about the child. The Teacher Knowledge Project, which, like the PTLC, works with teachers across subject areas and age groups, operates study groups across the country (Rodgers, 2002). It, too, follows a process that moves from description of experience to analysis to “intelligent action.” Based on Dewey’s conception of reflection, teachers are encouraged to “slow down” to see students and their learning. While the purpose of these two programs is not explicitly the development of the teacher’s self and identity, by training teachers’ attention on what is, rather than what they think should be or what they wish were so, these programs bring into focus the ways in which the fears and desires of the self can make assumptions which might not be borne out by evidence. They are then confronted with the gap between what is and what either they or the system thinks should be. The challenge then becomes one of choice—to act according to one’s own perceptions of what is necessary or according to the demands of the system.
Finally, it seems important to include in this discussion the work of Parker Palmer. With the Fetzer Foundation, Palmer has established a series of workshops and retreats that ask, “Who is the self that teaches? How does the quality of my selfhood form—or deform—the way I relate to my students, my subject, my colleagues, my world? How can educational institutions sustain and deepen the selfhood from which good teaching comes” (Intrator, 2002, p. 288). Palmer (1998), a college professor, writes, “In every class I teach, my ability to connect with my students and to connect them with the subject depends less on the method I use than on the degree to which I know and trust my own selfhood—and am willing to make it available and vulnerable in the service of learning” (p. 11). His workshops draw upon teachers’ “personal stories, reflections on classroom practice, and insights from poets, storytellers, and various wisdom traditions” (Intrator, 2002, p. 288). Palmer views teacher formation as a spiritual (though not explicitly religious) practice and intentionally structures his work with teachers along a retreat model. Time and space is built in for contemplation and solitude within a context of supportive community.

Analysis

These model teacher education and professional development programs share the following expectations: (1) teachers must know themselves and their own frames of reference, values and biases; (2) teachers should take a critical look at themselves and the privileges and inequities of their own and their students’ lives; (3) teachers should explore their own social perspectives; (4) teachers should reflect upon their educational experiences as children, and recognize how these experiences impact upon how they think about teaching; (5) teachers should be exposed to perspectives different from their own. Some consider the capacity to engage in this kind of self-reflection to be an “ethical necessity.” Each program offered processes that both challenged and supported teachers in confronting and changing their practices and conceptions: i.e. in developing their teacher selves and identities.

Constructive developmental theory helps us unpack the hidden developmental demands of these teacher education programs. It reveals that even model programs may not be good matches for all teachers who are enrolled (Berger, 2002, Drago-Severson, 2004, Kegan, 1982, 1994) and it highlights the importance of attending to the developmental diversity of students enrolled in such programs. As such, to assume that there is a static notion of identity or self puts even the best teacher education programs at risk for alienating certain groups of students.

These model teacher education programs may be best suited to the prospective teacher who is making sense somewhere between a stage three and a stage four way of knowing. For the stage three/stage four student, such programs provide the three necessary components of a “holding environment” that is designed to support the growth/development of its members’ selves.

A holding environment is a tricky transitional culture, an evolutionary bridge, a context for crossing over. It fosters developmental transformation or the process by which the whole (“how I am”) becomes gradually a part (“who I was”) of a new whole (“how I am now”).

(Kegan, 1994, p. 43)

These programs provide support (“to affirm the validity” of one’s experiences), challenge (to “open a gap between students and environment, a gap that creates tension in the
student—calling out for closure”) and vision (Daloz, 1999) suited to this subgroup of
students. In his discussion about the supportive function of mentors to adult learning
Daloz defines vision:

It [providing vision] is similar to Kegan’s idea of the confirming function. Mentors
hang around through transitions, a foot on either side of the gulf; they offer a hand to
help us swing across. By their very essence, mentors provide proof that the journey
can be made, the leap taken. In helping their charges look ahead, form a dream,
sketch their own maps, mentors offer a fair chance of ‘winning through’ as the Old
Man said to Telemakhos.

(p. 207)

These teacher education programs (appreciating the stage three side of students) pro-
vide a context of affiliation by offering a defined set of values, a common purpose that
generates a common language, or a norm of which students can be a part. As such, there
are clear values, expectations, and purposes that are defined by the program. This creates
a safe space in which students can begin to define themselves and their own purposes. The
challenge function of these teacher education programs (appreciating the student’s
movement towards a more self-authoring self) is the encouragement for students to
engage in self-reflection, to know/understand the limits of their own thinking, values,
histories, and the ways in which these limitations could influence their teaching. As such,
there is encouragement/support for students to become self-authoring. Finally, the vision
function of these programs is the belief that students’ teaching holds a bigger purpose; it
is for the greater good of a democratic society.

If prospective teachers are making sense in a stage 3 way (the socialized self, according
to Kegan), they are likely to feel “in over their heads” (Kegan, 1994). As a result, they
may experience disappointment and frustration because the program did not provide the
degree of clarity or the specific guidelines and direction that the students felt they needed.
The teacher educators may also experience disappointment and frustration because, in
their view, their students should take more risks, be independently minded, and refrain
from leaning on them. Teacher educators may desire their students to be more “self-
authoring” than they are capable of being. As such, there is a developmental mismatch
between the students and the developmental demands of the program. Using Daloz’s
model, the programs offer high challenge and low support. Unless supports are put
into place—a developmental bridge that attends to both who the teacher is now (her
current way of making meaning; stage three), and to who she may become (stage 4, a
more self-authored self)—students may disengage. (Daloz, 1999; Kegan, 1994).

It is also possible for prospective teachers operating in a stage four way (self-authoring)
or beyond to feel alienated in these model teacher education programs. While these
programs espouse values such as independence, self-motivation, and the capacity for self-
reflection/self-critique, they assume that students will espouse their values and beliefs
about teaching. Thus, a conflicting message is put forth. On the one hand, independence
and self-authoring are desired; yet, there is an unspoken expectation that students will
tow the party line (a stage three way of knowing). As a result, students who are
independent-minded, and hold a different set of values about teaching may, in fact,
challenge the very fabric of the program. These students may feel that asserting their
voice puts them at risk within the context of the program (i.e. maintaining the good
graces of their professors, achieving good grades, getting along with fellow students).
Because they hold a perspective on their conflict, they can make a conscious choice about
whether to “play the game” to get through the program successfully, to take the risk of
asserting their voice, or to leave the program. Teacher educators who themselves are not stage 4 or beyond may experience these students as a threat to the program, resistant (to upholding the values of the program), or self-absorbed. Using Daloz’s model there is low challenge and low support; unless both support and challenge are increased, there is the potential for disengagement.

Constructive developmental theory, then, helps us to better understand why some students’ may fare better than others in these model teacher education programs (Berger, 2002; Drago-Severson, 2004; Kegan, 1982, 1994). This perspective suggests that if our mission is to design teacher education programs that will support the growth and development of teacher selves, we need to attend to the developmental diversity students bring, as well as the developmental demands inherent in the program. A developmental perspective helps us to “see more clearly” and to have greater compassion for prospective teachers (Kegan, 1982). Rather, than focusing on behaviors (e.g. needy, resistant, etc.), we can attend to the meaning that these behaviors have to the students who are displaying them. This attention leads to better understanding of students and compels us to develop teacher education programs that attend to the developmental diversity of its students. In doing so, we are more likely to achieve the goal of graduating teachers who have successfully developed their own voice, and who can take a critical perspective on their teaching.

Finally, a note of caution. Implicit in this discussion is the notion that the growth and development of teachers’ selves is a worthy goal. It is the mission of these programs for students to become more self-authoring, self-motivated, and self-directed. However, prospective teachers leave these programs to enter school contexts that may, in fact, value a more stage three way of knowing. Schools, in fact, may prefer that their teachers enact a role that has been defined by the system, rather than that they self-author their role (see Achinstein and Ogawa, 2006 for an exploration of just this). Teachers who enter the system hoping to define their role may be at risk for a developmental mismatch between themselves and the context in which they find themselves teaching. Thus, teacher education programs must also give consideration to the developmental demands of the educational system and how to prepare students to negotiate that system in a way that is productive for them and their students.

CONCLUSION

In this chapter we have sorted through recent conceptions of teacher identity and teacher self to arrive at a new definition of teacher identity and teacher self. As we stated earlier, we define self to subsume teacher identities and to be an evolving, yet, coherent being that consciously and unconsciously constructs and is constructed, reconstructs and is reconstructed in interaction with cultural contexts, institutions, and people with which the self lives, learns, and functions. Drawing upon the psychological literature of constructive developmental theory, we highlight that the sense the self makes of her experiences is distinctly different at different levels of meaning making (i.e. the varying capacities to take a perspective on oneself), and that these differences color how the teacher self makes sense of her teacher identity, emotions that are evoked for her within the context of her teaching, and the level of connection or involvement that she may feel as a participant in her teacher education program.

In the face of such developmental diversity, there is nevertheless a hidden developmental expectation or assumption held by teacher educators and teacher education program that teachers should, in fact, make sense of their experiences at a particular level of development. They assume that prospective teachers should have the capacity to be
self-authoring, and self-critical. In our discussion, we have emphasized that without attention given to the developmental diversity of students, both they and their professors are at risk for disappointment, and even disengagement.

Clearly, what is still missing from the literature and the field is empirical work that seeks to better understand the role of psychology in teacher education. While there is an evolving literature on teacher emotion, the literature that brings in the psychological development of the self to bear on the effectiveness of teacher education programs is in its infancy. It is our hope that over the next decade this research will evolve so that we can better answer the questions that we posed at the beginning of this chapter: (1) How might teachers go about making the psychological shift from being authored by these forces to authoring their own stories? (2) How might teacher educators facilitate this process? (3) What is the impact on the practice of teachers who participate in such programs? And finally, (4) What is the impact on their students’ learning?

NOTES

1 It is well beyond the scope of this chapter to do this exhaustively. Conceptions of the self and identity reside in nearly every field of study from psychology to philosophy, from literature to cognitive science.

2 We exclude stage 1, the latency age child, and stage 5, a developmental achievement that is not usually achieved until middle age or later.

Learning among colleagues
Teacher community and the shared enterprise of education

Joel Westheimer
University of Ottawa

In both Norwegian and Hebrew, the verbs “to teach” and “to learn” are etymologically inseparable. Teaching and learning in these two highly distinct tongues are two sides of the same pedagogical coin. One who teaches is also one who learns. Yet teachers are rarely—on a daily basis—afforded formal or informal opportunities for learning. And teacher education programs do not always prepare future teachers to also be future learners. Most importantly—for the purposes of this chapter—too few teachers are adequately prepared to learn from one another, and too few schools create the conditions where learning from colleagues might be possible. As Seymour Sarason famously noted in his classic 1971 text, The Culture of School and the Problem of Change, teachers cannot possibly create and sustain productive learning environments for students when no such conditions exist for teachers. What do cultures of shared learning, dialogue, deliberation, debate, and community look like? How do such contexts affect teachers and students? How can we prepare future teachers to develop and benefit from professional interactions with colleagues?

This chapter reviews past and present conceptions of teacher professional communities as they relate to teacher learning. It conceptualizes teacher colleagues as a specific context for and resource to teacher learning. I emphasize empirical work that grounds these conceptions in actual teacher practice—in particular, the ways studying teacher practices exposes embedded values and competing ideologies. In what follows, I provide a brief history of these conceptions and review the multiple goals and enduring tensions inherent in studying and implementing teacher learning communities in practice.

A note about words

Many authors observe that terms such as “teacher community,” “teacher professional community,” and “professional learning community” are often used interchangeably in the literature that addresses teachers’ work in schools (Furman & Mertz 1997; Little & Horn 2006). Talking about teachers’ collaborative and collective work in schools, therefore, is slippery work. To make matters more complicated, these same terms are sometimes used to describe teachers’ work outside of schools, in professional networks and summer workshops. For example, the professional community of English teachers and the Portfolio Assessment teacher community can both boast a constituency concerned with teaching and learning. Furthermore, “professional” is used in varied ways. For example, some use the term specifically to distinguish technical “training” that treats teachers like mindless rule-followers from respectful and thoughtful teacher education and practice (as in the professionalism of teaching). A number of authors also delineate friendly conversation from deeper dialogues aimed at mutual learning. Brian Lord (1994), for example, draws the distinction between conviviality and critical
colleagueship. Getting along with one’s colleagues, he argues, is not the same as seeing colleagues as a resource in the ongoing study and improvement of teaching and learning. Similarly, Lima (1997), and Jarzabkowski (2002) wrestle with the differences and similarities between teachers’ friendships and their professional relationships.

In this chapter, I am concerned primarily with those interactions among teachers that are related to teacher learning. I use the term “teacher professional community” to designate a group of teachers engaged in professional endeavors together (those endeavors oriented specifically around teacher work). I will use “professional learning community” and “teacher learning community” to designate a subset of the former group—those specifically focused on learning with and from colleagues, generally within a school site.

TEACHING AND LEARNING TOGETHER

In the past three decades, assumptions about teaching and learning have changed substantially. Shifts in cognitive science and new theories of teaching and learning altered the way researchers and practitioners see the process of education unfolding. At the classroom level, researchers began to consider the ways students construct knowledge in relation to their surrounding contexts (e.g. Bruner, 1996; Gardner, 1985; Lave & Wenger, 1991; Vygotsky, 1978). And teacher educators began to emphasize the social and interdependent nature of teacher learning. Communities of learners became a popular way to think about not only students learning together but teachers collaborating as well (Barth, 1990; Sizer, 1992). Hoping to overcome the professional isolation so common in what Dan Lortie described as “egg-crate” schools (Lortie 1975)—where teachers are largely isolated from one another in their own classrooms—reformers began to advocate for new school structures and teacher practices that recognize the importance of learning within communities. By focusing on the environment in which teachers do their work, these reformers hoped to foster collegiality and increase professional dialogue.

The traditional view of schools as formal organizations began to give way, at least in some reform circles, to the notion of community. Research began to provide some evidence that examining schools as communities highlights “strategically different aspects of the school environment and fundamentally different levers for policy” (McLaughlin, 1993, p. 80; also Sergiovanni, 1994a). “The community metaphor,” writes McLaughlin, “draws [policy] attention to norms and beliefs of practice, collegial relations, shared goals, occasions for collaboration, problems of mutual support and mutual obligation” (1993, p. 81). By attending to teacher professional communities, researchers argued, we gain an understanding of the ways in which teachers’ relationships structure their work and their lives in schools. By the mid-1990s, creating professional conditions more conducive to a sense of collective mission and responsibility had become an essential component of many local, state, and national school reform efforts (Hargreaves, 1994; Lieberman, 1995; Meier, 1995; Sizer, 1992).

But while the goal of teacher learning within a community of colleagues is shared by many educators, the specifics of what these communities look like and of how to create and sustain them remain varied. The visions of teacher professional community implicit in school reform literature are numerous and diverse. Some variations are a matter of emphasis, creating complementary sets of lenses through which analysts can better study teacher communities in practice. Other visions, however, constitute competing ideologies about both the aims and means of professional learning communities in schools. The
The ambiguity of community

The anthropologist Herve Varenne (1986), while studying American conceptions of society and social diversity, concluded that there is tremendous theoretical confusion over notions of community. He found it difficult to reconcile ideals of individualism and community that coexist in the social psyche. Indeed, understanding the complexities inherent in these terms has been an ongoing project for more than two centuries. Contemporary examples of the tensions between individualism and community and between the borders of various communities abound. The readers of this book are undoubtedly part of multiple overlapping communities each of which has stronger or weaker bonds across numerous varied dimensions such as common beliefs, norms of interaction, participation, and space for dissent. Readers might be part of a “community of scholars,” a “community of teacher educators,” “the University of Pennsylvania community,” a “tenants community,” and their local neighborhood community, to name just a few.

For educators, the problems of conceptualizing community are multiplied. Necessarily occupying the space between theory and practice, researchers and reformers who study teacher professional communities often find conceptions of community rooted in practice to be oversimplified and those rooted in theory to be less than entirely convincing (Strike, 1999). Do three, four, or five characteristics constitute a way to identify communities, to verify that a particular alliance of individuals is or is not a community? Such a characterization would construe community as a static entity, and few social analysts would be comfortable with such a simplification. Many of the ethnographic accounts of teacher professional communities in practice go a considerable distance in providing a window into understanding the nature of experiences and interactions (Achinstein, 2002; Grossman et al., 2001; Little, 2003). But while the features commonly identified by social theorists provide a common language for recognizing communities and their constitutive elements, they do not define the community with generalizable rigor. More importantly, identifying these features rarely convinces others—especially those resistant to these reforms—of the benefits of community. Reading about community is a bit like reading about love—it falls short of the experience. Used in conjunction with vignettes and ethnographic analysis, however, the features identified in different visions contribute a great deal to the construction of a coherent framework for enabling and understanding teacher professional communities in practice.

THE MULTIPLE AND OVERLAPPING GOALS OF PROFESSIONAL LEARNING COMMUNITIES

Achinstein adapts a definition of teacher professional community from organizational theorists Van Maanen and Barley that succinctly reflects many of the proposed levers for change pursued by those seeking to foster professional communities in schools:

A teacher professional community can be defined as a group of people across a school who are engaged in common work; share to a certain degree a set of values, norms, and orientations towards teaching, students, and schooling; and operate
collaboratively with structures that foster interdependence (adapted from Van Maanen and Barley, 1984).

(Achinstein, 2002: 421–422)

The specific goals and processes suggested by particular visions of teacher professional community described in the research literature vary, but a number of them emphasize teacher learning and often refer to the teacher professional community as a professional learning community. As Mitchell and Sackney (2000) define it, teachers within professional learning communities “take an active, reflective, collaborative, learning-oriented, and growth-promoting approach toward the mysteries, problems and perplexities of teaching and learning” (Mitchell and Sackney, 2000). Below, I describe six umbrella categories that reflect common goals researchers and reformers have set for professional learning communities of teachers. Each of these perspectives draws on research findings that indicate the benefits and challenges for teaching and learning when teachers act in concert to “collectively question ineffective teaching routines, examine new conceptions of teaching and learning, find generative means to acknowledge and respond to difference and conflict, and engage actively in supporting one another’s professional growth” (Little, 2003, p. 914).

Although this section of the handbook of teacher education research emphasizes teacher learning, it is worth noting that there are other ways to frame the importance of teacher community. And there are other ways to conceptualize teacher learning beyond the narrow goal of student achievement as measured by standardized tests. Indeed, there is a small but significant body of work that critiques instrumental conceptions of teacher learning on the grounds that a narrow focus on instrumental goals (usually the idea that teacher learning will lead to improved student learning) crowds out other compelling reasons for a focus on strong communal relationships in schools (see, for example, Fielding, 1999; Hargreaves, 1994; Jarzabkowski, 2002; Nias, 1999). At the same time, a number of scholars and practitioners observe that not all professional communities are productive or even desirable. A group of teachers who meet every day and share meals on weekends but use their shared time primarily to complain about or deride students might arguably experience strong communal bonds, but not of the kind most reformers seek (Little & Horn, 2006; McLaughlin & Talbert, 2001).

Although there is substantial overlap in the groupings that follow (these perspectives are not intended to constitute discreet categories), they prove helpful in examining the scope of work that engages notions of teachers learning within a professional community. The sections that follow describe six interconnected goals that researchers and reformers have frequently cited in the quest for building, sustaining, and examining professional learning communities in schools. Educators interested in developing professional learning communities hope to: (1) improve teacher practice so students will learn; (2) make ideas matter to both teachers and students by creating a culture of intellectual inquiry; (3) develop teacher learning about leadership and school management; (4) promote teacher learning among novice teachers; (5) reduce alienation as a precondition for teacher learning; and (6) pursue social justice and democracy.

**Improve teacher practice so students will learn**

The most central, and commonly referenced goal for teacher learning communities is, not surprisingly, to improve teaching (Lieberman & Miller, 2004; McLaughlin & Talbert, 2001). The vision of teacher learning community that seeks most directly to improve teacher practice is perhaps most simply reflected in Little’s entreaty: “Imagine that you
would become a better teacher, just by virtue of being on the staff of a particular school—just from that one fact alone” (1987: 493). In a profession marked by endemic norms of privacy and independence (Little, 1990; Lortie, 1975; Pomson, 2005), the opportunities for teachers to learn from their colleagues are rarer than many would like (Smylie & Hart, 2000). The “egg-crate” structure of schools, the schedule of the school day, and the multiple conflicting demands on teachers make collaborative practice and reflection difficult. Schools that seek to break these norms hope that teachers will share the problems and successes they have with other teachers and take collective responsibility for students’ learning.

Kruse et al. (1995), for example, posit a framework for examining professional communities in schools in which “pedagogical growth and development of all teachers are considered a community-wide responsibility, and organizational structures such as peer coaching and time for conversation about practice are viewed as central” (1995: 27). The characteristics of successful professional learning communities, according to their framework, include a clear focus on student learning, reflective practice, deprivatized practice, collaboration, and shared values. Accordingly, the structural conditions necessary for teacher learning to occur include time to meet and talk, physical proximity to one another, interdependent teaching roles, structures for communication, and sufficient teacher autonomy (25). Professional learning communities like these nurture norms of collaboration and exchange that increase teachers’ opportunities to improve classroom practice (Louis & Marks, 1998; Little, 1999).

The literature is replete with variations on this theme and most of these characterizations of teacher learning communities are similar and complementary. Indeed, a number of excellent studies support the notion that given the proper organizational conditions for professional communities to remain strong, instructional innovation can be dramatically strengthened. For example, the University of Chicago’s Center for School Improvement studied elementary schools over a three year period and concluded that professional learning communities spur sustained reform in teaching practices in restructuring schools (Bryk et al., 1999). Lee et al. (1995) report on studies conducted by the Center on Organization and Restructuring of Schools of 11,000 students enrolled in 820 U.S. secondary schools. They found that in those schools that demonstrated characteristics consistent with strong professional learning communities, teachers’ classroom pedagogy was more likely to change in accordance with ongoing reform efforts. Similarly, McLaughlin and Talbert (1993) conducted longitudinal studies of high schools in California and Michigan and found that teacher professional learning communities are linked to instructional improvements and reform (see also McLaughlin & Talbert, 2001). Reyes et al. (1999) report on their work with Hispanic schools and also find that learning communities enabled teachers to improve their own practice. Over the past decade, other studies—both quantitative and qualitative—have supported these claims (Kruse & Louis, 1995; McLaughlin, 1993; Newmann & Wehlage, 1995; Sergiovanni, 1994b; Smylie & Hart, 2000; Thiessen & Anderson, 1999).

Student learning is also a central concern for those emphasizing teacher learning with and among colleagues. Accordingly, links to student achievement have been studied as well (Little, 1999; Louis & Marks, 1998; McLaughlin, 1993). In Successful School Restructuring, Newmann and Wehlage (1995) report on four large-scale studies that, together, include surveys of 1,500 elementary, middle, and high schools across the United States. The studies are notable for their extensive and careful data including surveys, three- and four-year longitudinal case studies, and compilation of student test results. Field research took place in 44 schools in sixteen states. In summarizing these studies (the National Educational Longitudinal Study of 1988, the School Restructuring Study, the
Study of Chicago School Reform, and the Longitudinal Study of School Restructuring), the authors link successful professional learning communities to reduced dropout rates among students, lower absenteeism rates, academic achievement gains (as measured by standardized tests) in math, science, history, and reading, and reduced gaps in achievement gains between students of varying socio-economic backgrounds. Together, these studies provide significant evidence that student learning depends, at least in part, on “the extent to which schools support the ongoing development and productive exercise of teachers’ knowledge and skills” (Smylie & Hart, 2000: 421).

Another promising practice for school-based teacher learning communities involves teachers examining student work collectively rather than individually (Little et al., 2003). A number of projects with that explicit focus have emerged in the past few years. One such project, for example, aims to “build the capacity of school faculties to improve the quality of instruction . . . through a continuous, comprehensive, and critical review of student work” (Academy for Education Development, 2006). Little and colleagues found useful aspects of professional learning communities built around examining student work to include: a process of localizing more generic tools for looking at student work, a healthy balance between comfort and challenge among the teachers, opportunities to use subject matter expertise, and strong and structured group facilitation to build relationships (2003: 189–190). Others have described similar teacher interactions around examinations of student work as fundamental to teacher (and student) learning within learning communities (see Ball & Cohen, 1999; Ball & Rundquist, 1992; Little, 1999; Sykes, 1999).

Studies have also made claims about the relationship between the specific nature and content of discussion among teachers (often called “teacher talk”) and the benefits of such exchanges for teacher and student learning. These studies seek to distinguish teacher talk that is generative of teacher and student learning from simple conversation (e.g. Achinstein, 2002; Little & Horn, 2006). Brian Lord’s model for “critical collegueship,” for example, specifies three concepts that should be reflected in teacher talk and exchange if the professional learning community is to reflect growth in teacher and student learning. First, teachers need to be open to discussing conflict and different views about teaching. He deems this conflict, if it is useful conflict, “productive disequilibrium” (Lord, 1994: 192). Second, he stresses that teachers need to become increasingly familiar (and comfortable) with ambiguity. And third, given the open conflict and ambiguity that he hopes will strengthen and not weaken the community, teachers must seek what Lord calls “collective generativity” (193) or a collective commitment to continuing their work together amidst ambiguity and conflict. Similarly, Ball and Cohen (1999) draw from case studies of teachers engaged in site-based professional development to provide thoughtful analysis of teachers’ exchanges around both joint and individual work. They argue that teacher learning is greatly enriched by grounding professional development in the daily particulars of teacher practice. Meaningful teacher discussions around their practice, Ball and Cohen suggest, especially when situated within assumptions of critical collegiality, strengthen teacher learning opportunities and reinforce the practical basis for teacher growth (see also Gray & Rubenstein, 2004; Hord, 2003; King, 2002; Little & Horn 2006).

Make ideas matter—a culture of intellectual inquiry

Although improving teacher practice is often a primary goal of efforts to foster teacher learning communities in schools, conceptions of teacher learning communities do not all put this goal front and center. A number of other visions of collective teacher learning and
practice hold strong sway in the literature. By focusing on teachers’ lived experiences in schools, many school reforms and teacher community research efforts seek to highlight other levers for change. Some reformers, for example, imagine a successful school-based professional learning community in the way Peter Senge describes it: “a meeting ground for learning—dedicated to the idea that all those involved with it, individually and together, will be continually enhancing and expanding their awareness and capabilities” (2000, p. 6). Although the literature I refer to here is certainly concerned with improving teaching, the immediate goal is to foster a professional culture of intellectual inquiry in the workplace by engaging teachers in collective reflection and exchange in matters of pedagogy and practice.

For example, some advocate subject matter inquiry for teachers, focusing on the teachers as students of their own discipline. Professional development that aims at deepening teachers’ disciplinary knowledge highlights a contrast “between the promise of direct applicability and the more distant goal of intellectual renewal” (Grossman et al., 2001: 952). The challenge, as Grossman and colleagues go on to explain, is “to maintain a focus on students while creating structures for teachers to engage as learners with the subject matters they teach . . . Teacher community must be equally concerned with student learning and with teacher learning” (952). Summer institutes for teachers have long provided intellectual stimulation for teachers in their subject areas, but this work necessarily occurs away from the professional community of the school. Having teachers engage in the difficult and rewarding work of intellectual renewal at the school site is an increasingly popular strategy for nurturing professional learning communities (Lieberman & Miller, 2004; Little et al., 2003; Smylie & Hart, 2000). Excellent examples of such practices abound, including a project bringing together humanities teachers to develop interdisciplinary curriculum through study of their own disciplines (Grossman et al., 2001), or subject-based reforms such as Project 2061 for changes in the science curriculum (American Association for the Advancement of Sciences, 1994).

These projects also meet with significant obstacles that I discuss in the section on enduring tensions. It is worth noting here, however, that those who study professional learning communities have become increasingly mindful about exploring and reporting on these tensions. One of the more detailed examples of this kind of reflective analysis can be found in Grossman and colleagues’ (2001) description of the complexities they encountered when working with a mixed group of English and history teachers in an urban Seattle high school. Bringing together these teachers for an “intellectual experience” building an interdisciplinary humanities curriculum, they found, was both rewarding and also fraught with difficulty. For example, they found that teachers—often not used to learning among colleagues—initially formed a “pseudo-community” in which everyone tended to behave as if they all agreed while skirting the substance of important disagreements and suppressing conflict. They also found that as they moved from pseudo-community to more substantive discourse, old tensions within the professional community that had been handily suppressed quickly rose to the surface. Studies by Achinstein (2002), Gunn and King (2003), and Uline et al. (2003) discuss similar challenges. Those reform projects that do not shy away from the challenges described in studies like these seem far more likely to succeed in fostering authentic cultures of intellectual inquiry and learning among teachers (Gray & Rubenstein 2004; Little & Horn 2006).

Another example of intellectual culture-building comes from the tradition of teacher research and university-school research partnerships. The ground-breaking work of Cochran-Smith and Lytle (1992b), for example, articulates the ways teacher inquiry not only improves the individual practice of teachers but also improves the collective
practices and culture of the entire professional community. More often than not, teacher research is concerned with the investigation of pedagogical practice rather than specific subject matter concerns. Teacher-scholars work together (often with the support and/or collaboration of university-based researchers) to examine their own practices, collectively study research done elsewhere, and challenge their own assumptions about teaching strategies, students, and broader educational policy issues (Hatch et al., 2005; Noffke & Stevenson, 1995). As Lieberman and Miller explain, because the research is local, it “resonates with the dilemmas of practice that other teachers experience” (2004, 29).

Some projects blend commitments to examining pedagogical and subject-matter concerns (see, for example, the Carnegie Foundation’s K-12 Academy for the Scholarship of Teaching and Learning [CASTL], www.carnegiefoundation.org/programs/index.asp?key=32). Indeed, Center for Research on the Contexts of Teaching researchers McLaughlin and Talbert and others have repeatedly found that strong professional learning communities are characterized by in-depth and ongoing discussions about curriculum and pedagogy in which teachers collectively examine ineffective teaching, and critique and challenge common practices (McLaughlin & Talbert, 2001; Little, 2003). Teaching, in these schools, is regarded less as individualized, rote, and technocratic work, and more as “highly intellectual work, grounded in professional communities where teachers assume responsibility for the learning of their students and of one another . . . a profession that views itself as an intellectual and collective enterprise” (Lieberman & Miller, 2005: 153).

These rationales for recognizing teaching as intellectual work and for building teacher learning communities that encourage intellectual exchange and that “make ideas matter” are deeply rooted in a sense of ethics about teachers as human beings in addition to the alleged efficacy for better practice that may result (for example, Ball & Wilson 1996). In summarizing Katz and Feiman-Nemser’s work on new teacher induction, for example, Goodlad and McMannon (2004) note that teachers are frequently told that they are in schools for students’ well-being. They argue that although this point seems self-evident and ordinary, creating an intellectually and morally sustaining environment requires “caring attention to one another and opportunities for continued [adult] learning” (96) and that this is not only a good idea because it helps to retain new teachers but also because,

it is simply the right thing to do. Sustaining a supportive environment should require no neon-lit slogans or ritualistic contingencies to remind us of the behavior our society should display. John Dewey taught us that traits such as civility, compassion, respect, and the like should be routine, reflective of cultural teaching and of learning what it means to be human.

(96)

Promoting a supportive environment by developing teacher learning communities is a theme also found in the literature about new teacher induction and early teaching experiences which I address later on.

**Teachers learning to be leaders**

I have noted the ways teachers within school-based learning communities engage intellectually with disciplinary content and pedagogical strategies for improving practice. Collectively examining and making decisions about school policies, leadership strategies, and school reform more broadly is another means reformers have touted for building intellectual engagement and on-the-job teacher learning. Many teachers describe the
larger political issues around schooling and discuss and write about their desire for
day-to-day decisions, engage in thoughtful inquiry, or collaborate are few (285). For reformers
advocating teacher leadership, inquiry goes beyond teachers learning their own discip-
lines or pedagogical approaches as described above. It has teachers learning to work
together as leaders of the school site.

Educational policymakers have recognized the importance of organizational design
and effective leadership in establishing and maintaining vibrant learning communities for
both teachers and students (Lieberman & Miller, 2004). Shared decision-making, collect-
ive action regarding school policies, and reflection on broader school reform issues are
seen as promising ways to engage teachers, foster collegiality, and improve practice.
Many school reformers now hope that teachers will become instructional leaders who
work and learn together across corridors, departments, and disciplines to foster edu-
cational reform (Barth, 2003; Lieberman, 1995; Leithwood, 2002; Maeroff, 1993). A
professional learning community can be a pre-condition for effective teacher leadership
and also be sustained by the collegial practices of teacher-led schools (Westheimer, 1998).

One of the enduring tensions in efforts to involve teachers in leadership positions is
what Little and Bartlett (2002) referred to as the “Huberman Paradox.” Michael
Huberman studied teachers’ career development and found that those teachers who
became involved in school and district leadership roles tended to suffer greater “burn-
out” than those who remained content to work only in their own classrooms with their
students (Huberman, 1993). As Lieberman and Miller (2004) summarize the paradox:
“on the one hand, teachers were stimulated by their involvement in reform work and
leadership in their school; on the other hand, that very work led to burnout, disaffection,
professional conflict, and disappointment” (p. 19). Other studies come to similar conclu-
sions (e.g. McLaughlin & Talbert, 2001; Johnson et al., 2004).

To a large degree, researchers and reformers suspect that the difficulties experienced
by teachers who take on leadership positions are due, in large part, to the absence of a
professional culture that supports collaborative leadership in the schools and local dis-
tricts. If, rather than individual teachers seeking to effect broad change, teachers worked
together in leadership roles, the benefits of collective teacher engagement could be real-
ized without the professional burnout that seemed to accompany individual efforts.
Building a collaborative culture, therefore, became a goal of those seeking to engage
teachers in leadership roles (Lieberman & Miller, 2004; McLaughlin & Talbert, 2001;
Lambert, 2003). And a number of studies have examined the ways school and district
administrators can create the conditions necessary for professional learning communities
to flourish for example by adjusting the school schedule so that teachers could have time
to meet together (Barth, 2003; Glickman, 2002). Working within professional learning
communities, reformers argue, teacher leaders can reinvigorate the work of teaching
for themselves and their colleagues, making it collaborative, purposeful, and dynamic
(Fullan, 1994; Hargreaves & Fink, 2006; Lieberman & Miller, 2004). Furthermore, the
kind of teacher learning that occurs in schools where teachers take on leadership roles
can serve as an additional counterforce to teacher burnout. When teachers experience
professional growth, they are more likely to stay in teaching (Nias, 1999; Strong & St.

Teacher learning for novice teachers

Teaching has long been characterized by unusually high attrition rates, especially among
new teachers (Lortie, 1975; Johnson et al., 2004). A number of studies indicate that some
50 percent of new teachers leave within the first five years of teaching (Grissmer & Kirby, 1997; Murnane et al., 1991). Moreover, teacher induction and retention programs have generally been far less structured and uniform than those of many other professional occupations. With some exceptions, a new teacher on her first day of school is often expected to perform the same or similar duties of a teacher who has been teaching for 25 years.

Further exacerbating the difficult first years of teaching, new teachers will spend a vast majority of their workday in isolation from colleagues in what many within the profession characterize as a “sink-or-swim” or “trial-by-fire” proposition (see Ingersoll & Kralik, 2004; Johnson et al., 2004; Kardos et al., 2001). This pervasive isolation leads to two kinds of recommendations pertinent to a discussion of teacher learning communities: first, new teachers require connections to veteran teachers in order to succeed in their first few years; and, second, most new and veteran teachers alike require a greater sense of connection and community to achieve the kind of personal and professional satisfaction that will keep them in the profession.

Susan Moore Johnson and colleagues in the Project on the Next Generation of Teachers at Harvard University conducted a longitudinal study of more than 50 teachers new to the teaching profession and found that the professional culture of the school greatly impacted novice teachers’ decisions about whether to stay in teaching or move on to other careers (Johnson et al., 2004). They identified three kinds of professional community (novice-oriented, veteran-oriented, and integrated) that offered varying levels of support to new teachers (Kardos et al., 2001). The consequences of veteran-oriented professional cultures—in which the teachers tend to split into camps of novice and veteran teachers—are dramatic:

In the first year of our study, twenty-one of the fifty new teachers taught within veteran-oriented professional cultures. Of those twenty-one, nine (43 percent) left their schools at the end of that year, and five (24 percent) left public school teaching altogether.

(Johnson et al., 2004: 150)

Similarly, in novice-oriented professional cultures—in which the community can be strong, but without a commitment to teacher learning—attrition can also be high. By contrast, in integrated professional cultures, novice and veteran teachers cohabit the professional community equally and orient their intertwined professional culture around sharing and improving practice. These schools emphasize “teachers as learners” (Johnson et al., 2004: 158) and their ability to retain teachers appears considerably higher than in either of the other two orientations (14 of the 17 teachers in their study who began their career in integrated professional communities remain in teaching).

Important studies by Sharon Feiman-Nemser and others have similarly shown the importance of professional collaboration and exchange, especially for new teachers. Mentoring, in particular—when practiced within a strong professional community—strengthens teacher retention, teacher learning, and pedagogical innovation (Feiman-Nemser et al., 1999; Gold, 1996; Katz & Feiman-Nemser, 2004; Strong & St. John, 2001; Smith & Ingersoll, 2004). It also helps novice teachers form and enact their own visions of good teaching and identify themselves with the teaching profession (Hammerness, 2006; Shulman & Shulman, 2004). This becomes especially important as routes into teaching proliferate and more new teachers enter the field without professional preparation.
Reduce alienation so teachers can learn from one another

Another issue affecting the ways both novice and veteran teachers learn on the job stems from broader cultural concerns over growing alienation (Bellah et al., 1985; Selznick, 1992; Wehlage et al., 1989). Scholars cite rampant individualism and isolation from one another as a growing impediment to our collective health (e.g. Putnam, 2000). Amitai Etzioni’s communitarian movement, for example, seeks to remedy these ills (Etzioni, 1993). Through association and interaction, psychologists observe, human beings satisfy their need for attachment and social bonds (Bronfenbrenner, 1979; Erikson, 1963). Similarly, sociologists and political scientists emphasize the sense of identity and the commitments that result from participation in community. Human experience, notes Dewey (1938), is inherently social, and therefore depends on interpersonal contact and collaboration within community.

Schools, many argue, must provide this sense of connection and purpose since traditional sources for connectedness have diminished. And teachers, as much as students, require these attachments in order to live out satisfying professional lives in schools and create conditions of community for students. Reflecting the work of sociologists and anthropologists who have long been interested in the ties that bind people together, reformers aim to have teachers form learning communities that inspire their work and enrich the connections among themselves and their students (Lieberman, 1995). They hope teachers will work collaboratively on projects they find meaningful. Teachers might meet during lunch, after school, and during free periods of the day to discuss curriculum, pedagogy, and individual students. Rather than the isolation and professional alienation that is common in many schools, these teachers might experience a sense of membership and belonging, thereby strengthening the profession. Consequently, the role of trust (Bryk and Schneider, 2003) and friendship (Lima, 1997; Jarzabkowski, 2002; Hargreaves, 1994) among teachers in professional learning communities have also been explored. The central goal of these efforts is to nurture and sustain a professional culture that offers the sense of belonging, association, and fellowship that makes it possible for teachers to learn from one another and experience a sense of growing professional expertise (Bryk & Schneider, 2003; Pomson, 2005; Uline et al., 2003).

However, it is not only to attract and retain teachers or to improve teacher practice and student test scores (all overly narrow and instrumental purposes some suggest) that scholars adopt the discourse of community. The community metaphor for educators, social theorists, and philosophers, is also intimately entwined with notions of democracy, social justice, and visions of the good society. I take up these views in the following section.

Pursuing social justice, democracy, and a communal way of life

A number of writers find the language of “professional” learning community potentially limiting in its focus on narrowly pragmatic or technocratic goals (e.g. Zeichner, 1991; Fielding, 1999; Hargreaves & Fink, 2006). Indeed, the word “professional” can demand attention to technical expertise rather than to broader social and socio-political commitments, especially when “professional” is tied to improving student test scores among students (as is increasingly the case among policy makers). Visions for teacher community, some authors suggest, should reflect the importance of democratic communities in pursuit of a better society. For example, Amy Gutmann, in her seminal work, Democratic Education (1987), argues that educators aiming at schooling that reinforces democratic notions of community must “create the conditions under which teachers can cultivate the
capacity for critical reflection on democratic culture” (Gutmann, 1987: 79). Fielding (1999) ties his vision for teacher collegiality (which he calls “radical collegiality”) to “an educational practice intentionally and demonstrably linked to the furtherance of democracy,” “communal practice,” and “educative engagement with each other and the world around us” (pp. 17–18). Fielding’s suggestions are more thematic than tied to the actual practices of schooling (the power of peer learning, students as teachers and teachers as learners, reconstructing education as a democratic project, and so on), but he is aligned with other scholars and education writers who suggest similar ties between education, democracy, and teacher community in schools (Clark & Wasley, 1999; Furman & Mertz, 1997; Hargreaves, 1994; Meier, 1995; Pomson, 2005; Westheimer, 1998).

Democracy, in this sense, is more than a means for collective decision making. Rather it is consistent with what Strike (1999) describes as “thick democracy” signifying,

a form of human community in which human flourishing is best realized and which is, therefore, essential to a good life. Thick democracy agrees that democratic practices promote fair decision making, but its value goes well beyond this. Thick democracy attaches significant value to such goods as participation, civic friendship, inclusiveness, and solidarity.

(Strike, 1999: 60)

What, then, would it mean for schools to pursue as an educational goal, a vision of “thick democracy”? The intellectual origins of school community as a (thick) democratic endeavor stem at least as far back as John Dewey and fellow turn-of-the-century progressives. “Democracy,” Dewey wrote, “is more than a form of government; it is primarily a mode of associated living, of conjoint communicated experience” (1916: 87). Schools thus require activities that have “social aims” and “utilize the materials of typical social situations. For under such conditions the school becomes itself a form of social life, a miniature community, and one in close interaction with other modes of associated experience beyond school walls” (Dewey, 1916: 360).

The path from Dewey’s philosophy of education to discussion of the conditions under which teachers live, work, and learn in schools is becoming increasingly well-traveled. Teachers should participate in developing democratic communities in schools that derive from collective projects. “Things gain meaning,” Dewey noted, “by being used in a shared experience or joint action” (1916: 16) and this line of argument can be found in a number of calls for greater attention to teacher professional communities in schools. As Hargreaves and Fink (2006) observe, it is either insincere or naive to expect students to “learn the important skills of living together in a pluralist society from teachers who—within the school at least—all too often lack the kinds of interactions and relationships with colleagues that embody just such constructive discourse” (15).

Notions of democratic community also imply notions of social betterment and social justice. In Democratic Education, for example, Amy Gutmann (1987) includes nonrepression and nondiscrimination as essential principles to uphold in any democratic education. The principles of nonrepression and nondiscrimination allow families and other community members to shape, but not entirely constrain, children’s future choices by obligating “professional educators to develop in children the deliberative capacity to evaluate competing conceptions of good lives and good societies” (46). Similarly, researchers and practitioners who view education as a means of transforming society often see teacher professional communities as a means of creating school cultures where both teachers and students learn how to promote just such transformation (Ayers, 2000; Fielding, 1999; Hargreaves, 1994).
Although some attention has been given to studying the possibilities for teacher community to advance a social-justice agenda, there has been little empirical work that seeks to assess the success or failure of such programs to effect change. Furthermore, much of the (non-empirical) discourse tends toward the saccharine—rhetorically sweet, but ideologically insipid. The values most often chosen as exemplars of teacher communities oriented towards social justice are those that produce maximum agreement, not necessarily those that are most reflective of philosophical or political notions of justice. “All children can learn” is far more likely to be a defining value of a teacher community aimed at “social justice” than values or goals that would likely engender controversy; and research to date has not, for the most part, sought to distinguish between teacher communities that pursue particular social justice agendas and those that do not. In other words, teacher communities (and studies that describe them) are more likely to boast a high degree of inclusiveness than strong adherence to a particular ideology that might foreground tensions around issues of social justice (see for example, Fielding, 1999).

ENDURING ISSUES AND CONCLUSIONS

Organizational management guru Peter Senge gained a great deal of attention for his 1990 book, *The Fifth Discipline*, which urged corporate America to consider developing “learning organizations.” In learning organizations, Senge explained, people continually learn from each other, “new and expansive patterns of thinking are nurtured,” and “collective aspiration is set free” (p. 3). The book made an impact on education researchers and practitioners who were engaged in their own efforts to effect change in schools. As Senge’s notion of the learning organization became incorporated into the literature on school reform, “learning communities” became the more popular term among educators.3

But schools are not corporate boardrooms and they rarely run like them. School administrators, teachers, teacher educators, and education researchers seeking to foster professional communities in schools face obstacles that have outlasted periods of significant reforms. Some of these obstacles are widely recognized in the literature (isolation, lack of time, school architecture, and external pressures such as standardized testing). Others are given short-shrift or avoided altogether (persistent tensions between strong shared beliefs and inclusiveness, micro-politics and conflict, and macro-politics and power). In the remainder of this chapter, I explore these continuing challenges to teacher learning communities in practice. In seeking to better understand the connections between teacher professional communities and teacher learning, these are the areas I suggest are in need of further study.

Isolation and the culture of privacy

Isolation and a culture of privacy in teaching has been one of the most persistent threads of inquiry and commentary in the teacher community literature. Empirical studies have repeatedly shown the difficulties involved in breaking norms of autonomy and privacy at the same time that they have shown the potential benefits of doing so for teacher learning. For example, when Hargreaves and colleagues (2006) asked teachers about obstacles they encountered in seeking to effect school change, the most prominent response teachers gave was having to implement these changes alone without the benefit of collegial professional dialogue. Similarly, Elmore and Burney (1999) found that the greatest “enemy of instructional improvement” is the isolation that most teachers experience during the school day (p. 268). And the isolation is enforced not only by the structural
conditions of teaching but also the cultural. What Little calls a “culture of isolation” is often internalized by teachers themselves who often feel too vulnerable or too busy to stop to learn from a colleague (Little, 1990, 1999). Pomson (2005: 787) sums up two explanations for teacher isolationism nicely—it is seen as either:

(a) an adaptive strategy in environments where the resources required to meet instructional demands are in short supply or (b) an ecological condition, encouraged by workplace settings where physical isolation is pervasive.

Teachers cannot learn from each other if they rarely see or talk to one another. Yet these are the working conditions in which teachers in many if not most schools find themselves. Numerous studies reinforce these disconcertingly conjoined truths: there is much to be gained by teachers working and learning through collective practice and reflection, and the culture of teaching and the organizational constraints on schools mitigate against such practices (for example, Bryk et al., 1999; Kruse & Louis, 1995). Indeed, as Cochran-Smith and Lytle found, the conditions of individual practice, on the whole, seem to be largely bolstered rather than challenged by organizational norms of the profession:

As a profession, teaching is primarily defined by what teachers do when they are not with other teachers. When teachers are evaluated, it is individual classroom performance that is scrutinized. When contracts are negotiated, it is amount of instructional time that is often a key issue. In fact, when teachers are out of their classrooms or talking to other teachers, they are often perceived by administrators, parents, and sometimes even by teachers themselves as not working.

(Cochran-Smith & Lytle, 1992a: 301)

Furthermore, the isolation is not limited to novice or veteran teachers, nor is it limited to schools of a particular demographic (Johnson et al., 2004; Lytle & Fecho, 1991). Despite two decades of reform efforts aimed at bringing teachers together in schools, many educators still observe that teacher work remains primarily private (Barth, 2003; Bredeson, 2003; Grossman et al., 2001).

Since the constraints on professional learning communities are not only organizational but also embedded in the professional culture, even when efforts to facilitate collaboration are implemented, resistance can be strong. In “Persistence of Privacy: Autonomy and Initiative in Teachers’ Professional Relations,” Little describes a phenomenon that is increasingly familiar to school reformers, staff developers, and teachers:

The most common configurations of teacher-to-teacher interaction may do more to bolster isolation than to diminish it; the culture that Lortie described as individualistic, present-oriented, and conservative is thus not altered but is indeed perpetuated by the most prevalent examples of teacher collaboration or exchange.

(1990, p. 511)

Feiman-Nemser and Floden (1986) reported similar disparity. The “cellular” nature of teaching in schools, they found, may be seen either as unfortunate lack of mutual support or as a welcome guarantee of professional autonomy (p. 517). Little and colleagues note that “Shared inquiry into student learning and teaching practice runs against the grain of typical professional talk and counter to the prevailing norms of non-interference, privacy, and harmony” (2003: 189–190). Management plans that grant teachers greater
decision-making authority often free teachers from bureaucracy but do not connect them to one another.

Another common theme in explanations for the persistent isolation of teachers is teachers’ own fears of exposure. In many schools, the expert teacher is considered to be the one who is confidently independent and self-sufficient (Cochran-Smith & Lytle, 1992b). Nervousness about evaluations or being embarrassed in front of peers or superiors result in many teachers preferring the isolation of their own classrooms to the perceived humiliation that might come from more collegial arrangements. Some teachers, even relatively novice ones, fear that if they ask too many questions, colleagues will perceive them to be less than competent (Richardson-Koehler, 1988; Pomson, 2005). These norms also help to explain the resistance to projects like video clubs, in which teachers videotape and discuss each other’s teaching (see Grossman et al., 2001).

How then do reformers address these obstacles? Researchers and school reformers have noted key strategies to overcoming the isolation so endemic to the profession of teaching. These include deliberately structured professional activities that require integrated work (Lieberman & Miller, 2004; Barth, 2003; Kahne & Westheimer, 2000), interdisciplinary teaching strategies that bring teachers together around content themes (Grossman et al., 2001), action research projects around shared interests (Cochran-Smith & Lytle, 2001), and organizational structures around subject-matter such as high school departments that encourage the exchange of ideas and mutual learning (Little, 1999; McLaughlin, 1993). Each of these strategies assume both that bringing teachers together to learn from one another will help to overcome persistent professional isolation and also that reduced teacher isolation (by changing the organizational structures of schooling, for example) will allow teachers to learn from one another.

Notably, the most transient and least successful efforts at bringing teachers together in shared inquiry tend to be those whose focus is on community-building itself in the absence of more intellectually or pragmatically substantive goals. Team-building, sunshine committees, shared lunchrooms, and after-school social gatherings are excellent supplements but poor substitutes for collective work on meaningful professional projects. Planning a shared curriculum unit together has been found to be a better approach to fostering teacher learning and dialogue than a lone event of introduce-your-neighbor (Barth, 2003; Kahne & Westheimer, 2000). A detailed and rigorous study in elementary schools by Cousins et al. (1994) found, for example, that in-depth joint work on curriculum planning and implementation among teachers resulted in significant conceptual and affective gains while casual conversation or occasional advice did not.

Strategies that challenge the culture of isolation common in the teaching profession are similar in approach and kind to strategies for broader school reform advocated in the past several decades. Reform efforts that seek to address some of the most intractable obstacles to developing and maintaining professional learning communities in schools aim towards many of the same levers for change: the organizational and administrative conditions discussed above, and the temporal and architectural structures of schools which I discuss below.

**Time and the pressures of standardization**

Time is a precious commodity for most teachers (Lortie, 1975; Johnson, 1990) and relationship-building is not a speedy process. Furthermore, building a professional community, especially around opportunities for teacher learning, can take up many (often unpaid) hours (Cochran-Smith & Lytle, 1992b; King, 2002). A number of researchers suggest that school reforms to increase available professional time for
teachers to spend together may well be a pre-condition for improved teacher learning (Bredson, 2003; Leithwood, 2002; Shollenberger-Swaim & Swaim, 1999). Teacher research, for example, is a prominent strategy to engage teachers in collective reflection on their own practice and widely understood as a potentially beneficial activity for teacher learning and community. But many teachers are hesitant to engage in teacher research for fear that it will take time away from their work with students (Cochran-Smith & Lytle, 1992b). Indeed, the most prominent examples of teacher learning take place outside of the school entirely. Teacher institutes and development seminars are most often stand-alone workshops in the summer or other non-instructional time. Teachers’ developmental learning is rarely integrated into the daily rhythms of the school day (King, 2002; Little, 1999; Cochran-Smith and Lytle, 1992).

Recent emphasis on standards and testing benchmarks further magnify the scarcity of time for teachers to pursue collective work. Highly restrictive, state-level curriculum frameworks, standards-based evaluations, and high-stakes testing for teachers and students can severely curtail new teachers’ capacities to teach as a community of colleagues who locate their teaching and curriculum development in the primacy of their own and their students’ experiences. Standards, high-stakes testing, and competency testing for both students and teachers are currently the noisiest and most prevalent educational conversations, and calls for developing learning communities or innovative collective teaching can be lost in the din. In the U.S., forty-nine states have now adopted higher academic standards as one of the major strategies for educational improvement (Clark & Wasley, 1999). Test scores are frequently used for decisions with regard to tracking, promotion, and graduation (National Research Council, 1999). Especially in districts where low test scores and high-stakes policies threaten students, teachers, and principals, a test-centered pedagogy and curriculum will frequently dominate (Brabeck, 1999; Shepard, 1991; Wiggins, 1993). In many cases, opportunities for collective leadership and reflection are constrained or focused solely on raising students’ test scores. In a study of 24 schools across 12 districts in six states, Berry and others found that “although high-stakes accountability systems help focus professional development efforts on the curricular needs of students, little evidence exists to support the claim that such systems help teachers change their practice to enhance student learning” (summarized in ASCD, 2004, p. 3). Furthermore, a “tendency exists—particularly in low-performing schools—to narrow the focus of professional development activities to tested subjects or provide general support that is disconnected from curricular needs” (3).

The inability of most teacher organizations to resist the onslaught of standards-based reforms and free up time to pursue broader visions of teacher and student learning hints at a related but infrequently mentioned issue regarding teacher professional community. Some authors express concern that the term “community” can be mis-used as a way to avoid the thornier issues of teacher professionalization, school funding, and low status of the profession (e.g. Meier, 2000; Zeichner, 1991). “Learning communities” cannot mitigate the fiscal crisis some schools now experience, these educators argue, and schools such as those described in Jonathan Kozol’s Savage Inequalities need adequate funding before talk about “getting along” or having teachers volunteer their time after school hours. Time and money may not be sufficient to move teachers from talk that is friendly to discussions that are generative of teacher learning, but many argue that they are necessary preconditions (Ayers, 2000; Sizer, 1992; Westheimer, 2000).

Similarly, research conducted as part of the Project on the Next Generation of Teachers, at Harvard University, makes clear that teachers’ lack of time impedes the formation of strong collaborative teacher professional cultures (Johnson et al., 2004). They point out that it costs money to provide the time and space for both new and veteran teachers to
meet and that matters of time and money are likely to be obstacles to community particularly in low-income and understaffed schools (see also Shollenberger-Swaim and Swaim, 1999 for the limitations of teachers’ time). Narrowing of the curriculum in response to testing mandates and adding extra “drill” classes on top of already burdened teacher schedules further restricts teachers’ opportunities for joint work and professional exchange (Kohn, 2000; Meier, 2000; Ohanian, 1999).

Architecture

Although public school reformers rarely have the opportunity to build a new school from scratch, many small-scale and private efforts have been able to make the architectural space of the school more conducive to both teacher–teacher and teacher–student interactions. And certainly, many educators have desired such changes (Meier, 1995; Barth, 1990; Sergiovanni 1994a). Probably owing to the lack of meaningful authority educators generally have over constructing the architectural plan of most schools, there have been few empirical studies of the effects of physical architecture on the learning environment and none of the effects on the capacities and predilections of teachers engaging in collegial learning activities. The small body of work that addresses the physical architecture of schools tends to narrowly emphasize healthy environments, air quality, heating, cooling, and so on (see, for example, Schneider, 2002).

There are some notable exceptions, such as Architecture for Education: New School Designs from the Chicago Competition (Sharp et al., 2003) and The Language of School Design (2005) by Nair and Fielding. Both works aim to connect research on teaching and learning to school planning and design strategies. Effective learning environments, the authors of these works argue, are dependent as much on the spatial arrangements of the school as they are on the curriculum. Nair and Fielding, for example, draw from Christopher Alexander’s classic work on “Pattern Language” to propose schools that reflect current concerns for learning communities, at least for students (see also Brubaker, 1997). Alexander’s groundbreaking work in the world of architecture sought to identify “patterns” in the built environment that seem to nourish human relationships, interplay, and exchange. In The Language of School Design, the authors apply Alexander’s theories to school design, hoping to address the “chasm between widely acknowledged best [educational] practice principles and the actual design of a majority of school facilities” (p. 2).

Other examples can be drawn from studies with foci on broader aspects of teacher professionalism and community. Scribner et al. (2002), for example, describe a school in which the principal decided to eliminate teacher classrooms and have teachers move around the school to their classes of students:

One thing the principal did that I think is very good was to eliminate the teachers’ desks in their rooms. Instead, we have a departmental concept. The teachers have all their desks in a room. The teachers didn’t like that, but the new ones, they don’t know any different. I don’t even know if she anticipated the benefit, but just by putting the teachers with each other, the new teachers are going to push the old teachers in some new ideas that they’ve got, and the old teachers are going to show the new teachers some of the neat things that do work.

(Veteran science teacher, quoted in Scribner et al., 2002, p. 68)

Their example demonstrates the considerable influence even small and inexpensive “architectural” decisions can make on the professional culture of the school.
One final area of inquiry that considers the impact of school architecture and organization on professional learning community is the small schools literature (Ayers, 2000; Raywid, 1996; Stevens & Kahne, 2006). The increased personalization and diminished complexity of small schools enables less bureaucracy and more interdependence between and among teachers, administrators, and students. A number of studies reinforce the findings of Bryk et al. (1999): “Among all the factors considered, small school size stood out as being an important facilitator of professional community . . . Professional community was much more prevalent in elementary schools with less than 350 students than it was in larger schools” (Bryk et al. 1999: 767; see also Darling-Hammond et al., 1995; Gladden, 1998; Raywid, 1996).

At the same time that certain forms of architecture may be correlated with teacher collaboration through the establishment of communal spaces, these spaces can also be seen as unwelcome efforts at containment or exclusion. School-within-school organizational structures, for example, can lead to tensions within the larger building and concerns over containment and isolation (Achinstein, 2002; Raywid, 1996). Moreover, in a study by Gunn and King (2003), one of the author’s classrooms was relocated to another floor, under the assumption that “Gunn and the other team member on Gunn’s floor were colluding together against the team leadership and that the close proximity of their classrooms was facilitating the formation of factions within the team” (Gunn & King, 2003: 182).

Overall, however, the literature on school architecture tends to be more metaphorical than literal. Bredeson (2003), for example, advocates new “architecture” for professional development in schools. Ideally, according to Bredeson, learning spaces for educators are not “isolated, self-contained spaces” but rather spaces that “support individual growth, foster collaborative learning, and build collective capacity” (p. 40). A number of others have observed the effects of spatial arrangements on teacher learning and collaboration as well (Glickman, 2002; Leithwood, 2002; Raywid, 1996; Rosenholtz, 1989). It is these often modest and/or metaphorical reforms to the physical space of the school coupled with the organizational and administrative reforms described earlier that have received substantial attention from educators and policy-makers interested in fostering learning communities for teachers.

**Tension between community and liberal inclusiveness**

Popular models for community generally demonstrate strong insights into the practical and theoretical tributaries that those interested in building community in schools must cross. Most, however, are less clear when discussing the social and political forces that often turn tributaries into quagmires. Nowhere is this more evident than in the considerable gloss that has consistently represented much of the literature on teacher professional community when it comes to issues of beliefs, ideology, and conflict. For example, conceptions of diversity have been central to most discussions about school and teacher community. The literature is replete with mentions of “tolerance,” “multicultural perspective,” and “diversity of ideas.” But relatively few works address the tough dilemmas that emerge when practitioners pursue the ideals of democratic and egalitarian communities, hoping to become neither excessively insular nor aimlessly diffuse. Much of the research and practice relating teacher community to teacher learning advocates working together, overlooking differences, and creating friendlier, more open work settings for teachers. More work would be useful that studies power imbalances and the resulting sense of impotence that threaten to undo so many of these well-meaning reforms. In short, those of us who study teacher collaboration could benefit more from plodding
through the muck, the ambiguity, and the mystery of how communities succeed and fail to manage conflict and how they ensure full participation of members with a diversity of backgrounds and interests. More specifically, studies are needed that address at least two persistent and overlapping tensions: the simultaneous pursuit of inclusiveness and community; and the reluctance to engage competing ideologies and conflict.

The tension between community and inclusiveness when it comes to professional learning communities is rooted in a gap in the broader schools-as-communities literature. This literature, as Strike (1999) points out, has not “adequately come to terms with the difficulties involved in sharing values in the public schools of a liberal democratic society” (p. 47). While most reformers advocate shared values as a basis for teacher community (Fielding, 1999; Little, 1999; Sergiovanni, 1994a), few engage what Strike notes is a tension between constitutive values and liberal inclusiveness. Constitutive values (values that are coherent enough to constitute communities among teachers and students), Strike explains, represent those beliefs and ideals people share about the good life and about ways schools might contribute to it. Catholic Schools are prima facie examples of schools with strong constitutive values because “those who are members of Catholic School communities can share a common educational project. They know what they are about because they have a shared vision of a good life and of how learning contributes to it” (p. 50). But, if we think towards extremes, no community can be wholly united by shared values and still be entirely inclusive. Indeed, anthropologists have long noted that communities are defined by their borders. Who is excluded is as important as who is included.

There have been a few responses to this dilemma, and I will describe just two here. Strike (1999) suggests a middle ground that calls for constitutive values that are “thick” enough to constitute community but vague enough to allow for competing ideas from all members of the community:

the standard of liberal inclusiveness does not so much reject constitutive values as it wants to privatize them. Liberals often value community. They reject communities whose values are made obligatory . . . for those who do not share them.

(Strike, 1999: 68)

Strike advocates building more opportunities for a middle ground that arises from greater freedom-of-association within public schools and public spaces. “Houses” within public schools, for example, could offer homes to students and teachers with varying but still constitutive conceptions of the good life. Given a number of different houses with varying degrees of constitutive ideals, no one, presumably, would be excluded from the school community entirely or branded second-class citizens.

A second response is illustrated by the work of Scribner et al. (2002). These authors argue that professional autonomy and individual needs, rather than being in conflict with community, might actually serve as necessary conditions that make professional community possible. They observe that much of the literature on professional community assumes a concordance between the health of the community and the degree to which collective identity supplants individual identity and needs (p. 49). They suggest that a more salient frame for examining the strength of professional community might be named a shared identity among heterogeneous individuals engaged in professional relationships rather than a collective identity that, as they see it, requires giving up individual autonomy and needs. Professional autonomy and attention to individual needs, the authors argue, are necessary conditions for strong professional communities where teachers can and do learn from one another. They describe one school in which the
principal sought to impose a collective identity among teachers and was rebuffed. The teachers saw the imposition of collective action as a threat to their professional autonomy. In another (preferred) school, the principal encouraged a shared identity ("we-ness") that protected teachers' individual needs and their professional autonomy ("I-ness") and therefore resulted in a strong sense of professional community where shared teacher learning became the norm.

I make a related observation in Among Schoolteachers: Community, Autonomy, and Individuality in Teachers' Work (Westheimer, 1998). In describing two professional communities of teachers (Brandeis and Mills schools), I acknowledge a common tension and fear: that within a community with shared beliefs and interests, individuality will be suppressed and the individual submerged into a monolithic whole (p. 146). But the Mills community seemed to demonstrate something else at work entirely: individuality and community were unexpected bedfellows in the quest for a professional learning environment:

Among the teachers, administrators, and staff at Mills are the usual gamut of individuals as well: the gregarious and the reserved, the associated and the isolated, those who stand out and those who prefer to blend in. [But these identities] call into question critics’ customary polarization of the individual and the collective . . . I learned an extraordinary amount about individuals’ multiple roles in the community [and] their identities in relation to the community. Walter is known for speaking quietly. Paul builds wheelchairs. Mark is a workhorse. Sabrina is active in local community politics and can be counted on to bring important aspects of her work to bear in curriculum development for the school.

Collective projects at this school showcase teachers’ talents and model the use of these talents for social purposes. Rather than submerging the individual within the group, collective work and frequent and engaged participation provide an opportunity and forum to develop an individual identity within and in relation to the group. This allowed teachers to learn from each other’s different talents and capacities.

There are several other works that explore the tension between inclusiveness and community, and a small number do so empirically (Leithwood, 2002; Malen, 1995; Marshall & Scribner, 1995). This area, however, like the one that follows, is ripe for further investigation. In what ways can collective projects among teachers further teacher learning and development? How might communal identities be forged without sacrificing individual teachers’ sense of autonomy? What role can school leaders play?

Reluctance to engage competing ideologies

The beliefs about teaching and learning that teachers, administrators, school board members, and parents share affect the curriculum, the organization, and the values conveyed to students about the purposes of education (Hargreaves & Fink, 2006; Strike, 1999). These beliefs and orientations are visible not only in the content of the curriculum but also in the organization and practices of the teacher professional community in each school (McLaughlin & Talbert, 2001) and or smaller units within the school such as high school departments (Siskin, 1994). Learning among teachers is accordingly affected by the embedded priorities and emphases of the broader professional community. One teacher professional community might emphasize teachers’ individual autonomy, rights, and responsibilities to colleagues while another might be driven by a strong collective mission and collective values. One group of teachers might work together to develop
interdisciplinary joint curriculum while another might convene in order to help individual teachers pursue individually-defined curricular goals. In contrast to so many school, both of these examples (and there are surely more) represent communities in which teachers do not feel isolated, share opportunities for learning from one another, and may be content in their jobs. But the differences are consequential: ideologically, different forms of learning communities embody differing beliefs about the purposes of professional communities, the philosophical, social, and political beliefs, values, and opinions that shape the way a group of teachers view the world, and the broad purposes of education in pursuing those beliefs.

Even the names various schools use to describe the ways their teachers work together can be revealing. A “team,” for example denotes an instrumental group where individuals come together to accomplish a task. Other schools might divide teachers and students into “families,” implying that individuals are part of a collective. In teams, individuals can accomplish goals together that may be unattainable alone. In families—ideally—individuals gain a sense of connection, belonging, and affinity.

When researchers study the effects of teacher communities on teacher learning, it would be useful to further distinguish empirically between teacher learning in these different kinds of learning communities. Many argue that teachers should share beliefs to form a robust professional community, but few articulate which beliefs might be worth sharing. “What beliefs should be shared?” is a thorny question almost always left to the imagination of practitioners and policy-makers. When it comes to specifying the kinds of beliefs that might lead to particular kinds of teacher learning and exchange, the literature on professional learning communities remains largely—to borrow Little’s description of collegiality (1990)—“conceptually amorphous and ideologically sanguine” (p. 519).

Researchers and reformers often assert the role that sharing beliefs plays in community-building while ignoring the importance of the nature of the beliefs themselves and how these beliefs might bring about different kinds of learning. Developing not only clear conceptualizations of learning communities but also of the specific values, commitments, and ideologies that such conceptualizations embody could significantly strengthen practical efforts to build professional learning communities among teachers in schools (Cochran-Smith, 2001; Westheimer, 2000).

FUTURE RESEARCH

The literature on how teachers learn with and from colleagues has evolved significantly in the 20 years or so since discussions about professional learning communities became common. A variety of school reform efforts depend on teachers’ ability to work with and learn from colleagues (Lieberman & Miller, 2004). Yet teacher education and development has only just begun to serve as a focus for developing learning communities. Schools led by communities of teachers who are responsible for making curricular, organizational, and sometimes financial decisions require that teachers learn from one another and become well versed about the benefits, commitments, tensions, and trouble spots that emerge when people learn and work together in demanding environments.

Research has demonstrated links between professional learning communities for teachers and improved teacher practice and student learning; a climate of intellectual inquiry; teachers’ ability and willingness to serve as leaders; new teacher learning and retention; reduced alienation; and social justice and democracy. These studies provide significant rationale for continued work in the areas of professional learning communities.
Little and Horn (2006), for example, are currently studying teacher discourse to see what kinds of “teacher talk” are consequential and hold the greatest potential for teacher learning. More research of this nature would be beneficial to those seeking to understand the ways teachers learn from each other.

Moreover, enduring tensions persist and call for continued investigation. These include tensions around: isolation and privacy; time teachers have to engage in collaborative learning in a climate of standards and assessment; school architecture; inclusiveness; and varying ideologies. Research to date has indicated that amidst these tensions and without adequate preparation for teachers, expectations for teacher learning are easily thwarted (Lieberman & Miller, 2004).

Teacher learning among colleagues is a promising area for teacher development and reform. Further clarifying the substance and direction of teacher learning communities in practice is the task researchers and teacher educators now face.

NOTES

1 Research conducted for this chapter was supported by the University Research Chairs program at the University of Ottawa and through a grant from the Social Sciences and Humanities Research Council of Canada. Karen Emily Suurtamm provided outstanding research assistance, compiling and summarizing extensive swaths of literature. I would also like to thank Brad Cousins, Sharon Feiman-Nemser, Barbara Leckie, and Karen Emily Suurtamm for thoughtful comments on earlier drafts.

2 This observation is the subject of many biblical parables about teaching and is also described in Grossman et al. (2001).

6.1 The relation of theory to practice in education

John Dewey

It is difficult, if not impossible, to define the proper relationship of theory and practice without a preliminary discussion, respectively, (1) of the nature and aim of theory; (2) of practice.

A. I shall assume without argument that adequate professional instruction of teachers is not exclusively theoretical, but involves a certain amount of practical work. The primary question as to the latter is the aim with which it shall be conducted. Two controlling purposes may be entertained so different from each other as radically to alter the amount, conditions, and method of practice work. On one hand, we may carry on the practical work with the object of giving teachers in training working command of the necessary tools of their profession; control of the technique of class instruction and management; skill and proficiency in the work of teaching. With this aim in view, practice work is, as far as it goes, of the nature of apprenticeship. On the other hand, we may propose to use practice work as an instrument in making real and vital theoretical instruction; the knowledge of subject-matter and of principles of education. This is the laboratory point of view.

The contrast between the two points of view is obvious; and the two aims together give the limiting terms within which all practice work falls. From one point of view, the aim is to form and equip the actual teacher; the aim is immediately as well as ultimately practical. From the other point of view, the immediate aim, the way of getting at the ultimate aim, is to supply the intellectual method and material of good workmanship, instead of making on the spot, as it were, an efficient workman. Practice work thus considered is administered primarily with reference to the intellectual reactions it incites, giving the student a better hold upon the educational significance of the subject-matter he is acquiring, and of the science, philosophy, and history of education. Of course, the results are not exclusive. It would be very strange if practice work in doing what the laboratory does for a student of physics or chemistry in way of securing a more vital understanding of its principles, should not at the same time insure some skill in the instruction and management of a class. It would also be peculiar if the process of acquiring such skill should not also incidentally serve to enlighten and enrich instruction in subject-matter and the theory of education. None the less, there is a fundamental difference in the conception and conduct of the practice work according as one idea or the other is dominant and the other subordinate. If the primary object of practice is acquiring skill in performing the duties of a teacher, then the amount of time given to practice work, the place at which it is introduced, the method of conducting it, of supervising, criticizing, and correlating it, will differ widely from the method where the laboratory ideal prevails; and vice versa.

In discussing this matter, I shall try to present what I have termed the laboratory, as distinct from the apprentice idea. While I speak primarily from the standpoint of the college, I should not be frank if I did not say that I believe what I am going to say holds, mutatis mutandis, for the normal school as well.
I. I first adduce the example of other professional schools. I doubt whether we, as educators, keep in mind with sufficient constancy the fact that the problem of training teachers is one species of a more generic affair—that of training for professions. Our problem is akin to that of training architects, engineers, doctors, lawyers, etc. Moreover, since (shameful and incredible as it seems) the vocation of teaching is practically the last to recognize the need of specific professional preparation, there is all the more reason for teachers to try to find what they may learn from the more extensive and matured experience of other callings. If now we turn to what has happened in the history of training for other professions, we find the following marked tendencies:

1. The demand for an increased amount of scholastic attainments as a prerequisite for entering upon professional work.
2. Development of certain lines of work in the applied sciences and arts, as centres of professional work; compare, for example, the place occupied by chemistry and physiology in medical training at present, with that occupied by chairs of “practice” and of “materia medica” a generation ago.
3. Arrangement of the practical and quasi-professional work upon the assumption that (limits of time, etc., being taken into account) the professional school does its best for its students when it gives them typical and intensive, rather than extensive and detailed, practice. It aims, in a word, at control of the intellectual methods required for personal and independent mastery of practical skill, rather than at turning out at once masters of the craft. This arrangement necessarily involves considerable postponement of skill in the routine and technique of the profession, until the student, after graduation, enters upon the pursuit of his calling.

These results are all the more important to us because other professional schools mostly started from the same position which training schools for teachers have occupied. Their history shows a period in which the idea was that students ought from the start to be made as proficient as possible in practical skill. In seeking for the motive forces which have caused professional schools to travel so steadily away from this position and toward the idea that practical work should be conducted for the sake of vitalizing and illuminating intellectual methods two reasons may be singled out:

a) First, the limited time at the disposal of the schools, and the consequent need of economy in its employ. It is not necessary to assume that apprenticeship is of itself a bad thing. On the contrary, it may be admitted to be a good thing; but the time which a student spends in the training school is short at the best. Since short, it is an urgent matter that it be put to its most effective use; and, relatively speaking, the wise employ of this short time is in laying scientific foundations. These cannot be adequately secured when one is doing the actual work of the profession, while professional life does afford time for acquiring and perfecting skill of the more technical sort.

b) In the second place, there is inability to furnish in the school adequate conditions for the best acquiring and using of skill. As compared with actual practice, the best that the school of law or medicine can do is to provide a somewhat remote and simulated copy of the real thing. For such schools to attempt to give the skill which comes to those adequately prepared, insensibly and unavoidably in actual work, is the same sort of thing as for grammar schools to spend months upon months in trying to convey (usually quite unsuccessfully) that skill in commercial arithmetic which comes, under penalty of practical failure, in a few weeks in the bank or counting-house.

It may be said that the analogy does not hold good for teachers' training schools, because such institutions have model or practice departments, supplying conditions which are identical with those which the teacher has to meet in the actual pursuit of his calling. But this is true at most only in such normal schools as are organized after the Oswego pattern—schools, that is to say, where the pupil-teacher is given for a considerable period of time the entire charge of instruction and discipline in the class-room, and does not come under a room critic-teacher. In all other cases, some of the most fundamentally significant features of the real school are reduced or eliminated. Most “practice schools” are a compromise. In theory they approximate ordinary conditions. As
matter of fact, the “best interests of the children” are so safeguarded and supervised that the situation approaches learning to swim without going too near the water.

There are many ways that do not strike one at first glance, for removing the conditions of “practice work” from those of actual teaching. Deprivation of responsibility for the discipline of the room; the continued presence of an expert ready to suggest, to take matters into his own hands; close supervision; reduction of size of group taught; etc., etc., are some of these ways. The topic of “lesson plans” will be later referred to in connection with another topic. Here they may be alluded to as constituting one of the modes in which the conditions of the practice-teacher are made unreal. The student who prepares a number of more or less set lessons; who then has those lesson plans criticized; who then has his actual teaching criticized from the standpoint of success in carrying out the prearranged plans, is in a totally different attitude from the teacher who has to build up and modify his teaching plans as he goes along from experience gained in contact with pupils.

It would be difficult to find two things more remote from each other than the development of subject-matter under such control as is supplied from actual teaching, taking effect through the teacher’s own initiative and reflective criticism, and its development with an eye fixed upon the judgment, presumed and actual, of a superior supervisory officer. Those phases of the problem of practice teaching which relate more distinctly to responsibility for the discipline of the room, or of the class, have received considerable attention in the past; but the more delicate and far-reaching matter of intellectual responsibility is too frequently ignored. Here centers the problem of securing conditions which will make practice work a genuine apprenticeship.

II. To place the emphasis upon the securing of proficiency in teaching and discipline puts the attention of the student-teacher in the wrong place, and tends to fix it in the wrong direction—not wrong absolutely, but relatively as regards perspective of needs and opportunities. The would-be teacher has some time or other to face and solve two problems, each extensive and serious enough by itself to demand absorbing and undivided attention. These two problems are:

1. Mastery of subject-matter from the standpoint of its educational value and use; or, what is the same thing, the mastery of educational principles in their application to that subject-matter which is at once the material of instruction and the basis of discipline and control;
2. The mastery of the technique of class management.

This does not mean that the two problems are in any way isolated or independent. On the contrary, they are strictly correlative. But the mind of a student cannot give equal attention to both at the same time.

The difficulties which face a beginning teacher, who is set down for the first time before a class of from thirty to sixty children, in the responsibilities not only of instruction, but of maintaining the required order in the room as a whole, are most trying. It is almost impossible for an old teacher who has acquired the requisite skill of doing two or three distinct things simultaneously—skill to see the room as a whole while hearing one individual in one class recite, of keeping the program of the day and, yes, of the week and of the month in the fringe of consciousness while the work of the hour is in its centre—it is almost impossible for such a teacher to realize all the difficulties that confront the average beginner.

There is a technique of teaching, just as there is a technique of piano-playing. The technique, if it is to be educationally effective, is dependent upon principles. But it is possible for a student to acquire outward form of method without capacity to put it to genuinely educative use. As every teacher knows, children have an inner and an outer attention. The inner attention is the giving of the mind without reserve or qualification to the subject in hand. It is the first-hand and personal play of mental powers. As such, it is a fundamental condition of mental growth. To be able to keep track of this mental play, to recognize the signs of its presence or absence, to know how it is initiated and maintained, how to test it by results attained, and to test apparent results by it, is the supreme mark and criterion of a teacher. It means insight into soul-action,
ability to discriminate the genuine from the sham, and capacity to further one and discourage the other.

External attention, on the other hand, is that given to the book or teacher as an independent object. It is manifested in certain conventional postures and physical attitudes rather than in the movement of thought. Children acquire great dexterity in exhibiting in conventional and expected ways the form of attention to school work, while reserving the inner play of their own thoughts, images, and emotions for subjects that are more important to them, but quite irrelevant.

Now, the teacher who is plunged prematurely into the pressing and practical problem of keeping order in the schoolroom has almost of necessity to make supreme the matter of external attention. The teacher has not yet had the training which affords psychological insight—which enables him to judge promptly (and therefore almost automatically) the kind and mode of subject-matter which the pupil needs at a given moment to keep his attention moving forward effectively and healthfully. He does know, however, that he must maintain order; that he must keep the attention of the pupils fixed upon his own questions, suggestions, instructions, and remarks, and upon their "lessons." The inherent tendency of the situation therefore is for him to acquire his technique in relation to the outward rather than the inner mode of attention.

III. Along with this fixation of attention upon the secondary at the expense of the primary problem, there goes the formation of habits of work which have an empirical, rather than a scientific, sanction. The student adjusts his actual methods of teaching, not to the principles which he is acquiring, but to what he sees succeed and fail in an empirical way from moment to moment: to what he sees other teachers doing who are more experienced and successful in keeping order than he is; and to the injunctions and directions given him by others. In this way the controlling habits of the teacher finally get fixed with comparatively little reference to principles in the psychology, logic, and history of education. In theory, these latter are dominant; in practice, the moving forces are the devices and methods which are picked up through blind experimentation; through examples which are not rationalized; through precepts which are more or less arbitrary and mechanical; through advice based upon the experience of others. Here we have the explanation, in considerable part at least, of the dualism, the unconscious duplicity, which is one of the chief evils of the teaching profession. There is an enthusiastic devotion to certain principles of lofty theory in the abstract—principles of self-activity, self-control, intellectual and moral—and there is a school practice taking little heed of the official pedagogic creed. Theory and practice do not grow together out of and into the teacher's personal experience.

Ultimately there are two bases upon which the habits of a teacher as a teacher may be built up. They may be formed under the inspiration and constant criticism of intelligence, applying the best that is available. This is possible only where the would-be teacher has become fairly saturated with his subject-matter, and with his psychological and ethical philosophy of education. Only when such things have become incorporated in mental habit, have become part of the working tendencies of observation, insight, and reflection, will these principles work automatically, unconsciously, and hence promptly and effectively. And this means that practical work should be pursued primarily with reference to its reaction upon the professional pupil in making him a thoughtful and alert student of education, rather than to help him get immediate proficiency.

For immediate skill may be got at the cost of power to go on growing. The teacher who leaves the professional school with power in managing a class of children may appear to superior advantage the first day, the first week, the first month, or even the first year, as compared with some other teacher who has a much more vital command of the psychology, logic, and ethics of development. But later "progress" may with such consist only in perfecting and refining skill already possessed. Such persons seem to know how to teach, but they are not students of teaching. Even though they go on studying books of pedagogy, reading teachers' journals, attending teachers' institutes, etc., yet the root of the matter is not in them, unless they continue to be students of subject-matter, and students of mind-activity. Unless a teacher is such a
student, he may continue to improve in the mechanics of school management, but he can not
grow as a teacher, an inspirer and director of soul-life. How often do candid instructors in training
schools for teachers acknowledge disappointment in the later career of even their more promis-
ing candidates? They seem to strike twelve at the start. There is an unexpected and seemingly
unaccountable failure to maintain steady growth. Is this in some part due to the undue premature
stress laid in early practice work upon securing immediate capability in teaching?

I might go on to mention other evils which seem to me to be more or less the effect of this same
cause. Among them are the lack of intellectual independence among teachers, their tendency to
intellectual subserviency. The “model lesson” of the teachers’ institute and of the educational
journal is a monument, on the one hand, of the eagerness of those in authority to secure immediate
practical results at any cost; and, upon the other, of the willingness of our teaching corps to
accept without inquiry or criticism any method or device which seems to promise good results.
Teachers, actual and intending, flock to those persons who give them clear-cut and definite
instructions as to just how to teach this or that.

The tendency of educational development to proceed by reaction from one thing to another, to
adopt for one year, or for a term of seven years, this or that new study or method of teaching, and
then as abruptly to swing over to some new educational gospel, is a result which would be
impossible if teachers were adequately moved by their own independent intelligence. The will-
ingness of teachers, especially of those occupying administrative positions, to become sub-
merged in the routine detail of their callings, to expend the bulk of their energy upon forms and
rules and regulations, and reports and percentages, is another evidence of the absence of
intellectual vitality. If teachers were possessed by the spirit of an abiding student of education,
this spirit would find some way of breaking through the mesh and coil of circumstance and would
find expression for itself.

B. Let us turn from the practical side to the theoretical. What must be the aim and spirit of
theory in order that practice work may really serve the purpose of an educational laboratory? We
are met here with the belief that instruction in theory is merely theoretical, abstruse, remote, and
therefore relatively useless to the teacher as a teacher, unless the student is at once set upon the
work of teaching; that only “practice” can give a motive to a professional learning, and supply
material for educational courses. It is not infrequently claimed (or at least unconsciously
assumed) that students will not have a professional stimulus for their work in subject-matter and
in educational psychology and history, will not have any outlook upon their relation to education,
unless these things are immediately and simultaneously reinforced by setting the student upon
the work of teaching. But is this the case? Or are there practical elements and bearings already
contained in theoretical instruction of the proper sort?

I. Since it is impossible to cover in this paper all phases of the philosophy and science of
education, I shall speak from the standpoint of psychology, believing that this may be taken as
typical of the whole range of instruction in educational theory as such.

In the first place, beginning students have without any reference to immediate teaching a very
large capital of an exceedingly practical sort in their own experience. The argument that theor-
etical instruction is merely abstract and in the air unless students are set at once to test and
illustrate it by practice teaching of their own, overlooks the continuity of the class-room mental
activity with that of other normal experience. It ignores the tremendous importance for educational
purposes of this continuity. Those who employ this argument seem to isolate the psychology of
learning that goes on in the schoolroom from the psychology of learning found elsewhere.

This isolation is both unnecessary and harmful. It is unnecessary, tending to futility, because it
throws away or makes light of the greatest asset in the student's possession—the greatest,
moreover, that ever will be in his possession—his own direct and personal experience. There is
every presumption (since the student is not an imbecile) that he has been learning all the days
of his life, and that he is still learning from day to day. He must accordingly have in his own
experience plenty of practical material by which to illustrate and vitalize theoretical principles and
laws of mental growth in the process of learning. Moreover, since none of us is brought up under
ideal conditions, each beginning student has plenty of practical experience by which to illustrate
cases of arrested development—instances of failure and maladaptation and retrogression, or
even degeneration. The material at hand is pathological as well as healthy. It serves to embody
and illustrate both achievement and failure, in the problem of learning.

But it is more than a serious mistake (violating the principle of proceeding from the known to
the unknown) to fail to take account of this body of practical experience. Such ignoring tends also
to perpetuate some of the greatest evils of current school methods. Just because the student’s
attention is not brought to the point of recognizing that his own past and present growth is
proceeding in accordance with the very laws that control growth in the school, and that there is no
psychology of the schoolroom different from that of the nursery, the playground, the street, and
the parlor, he comes unconsciously to assume that education in the class-room is a sort of
unique thing, having its own laws. Unconsciously, but none the less surely, the student comes to
believe in certain “methods” of learning, and hence of teaching which are somehow especially
appropriate to the school—which somehow have their particular residence and application there.
Hence he comes to believe in the potency for schoolroom purposes of materials, methods, and
devices which it never occurs to him to trust to in his experience outside of school.

I know a teacher of teachers who is accustomed to say that when she fails to make clear to a
class of teachers some point relative to children, she asks these teachers to stop thinking of their
own pupils and to think of some nephew, niece, cousin, some child of whom they have acquaint-
ance in the unformalities of home life. I do not suppose any great argument is needed to prove
that breach of continuity between learning within and without the school is the great cause in
education of wasted power and misdirected effort.

I wish rather to take advantage of this assumption (which I think will be generally accepted) to
emphasize the danger of bringing the would-be teacher into an abrupt and dislocated contact
with the psychology of the schoolroom—abrupt and dislocated because not prepared for by prior
practice in selecting and organizing the relevant principles and data contained within the experi-
ence best known to him, his own.

From this basis, a transition to educational psychology may be made in observation of the
teaching of others—visiting classes. I should wish to note here, however, the same principle that I
have mentioned as regards practice work, specifically so termed. The first observation of instruc-
tion given by model- or critic-teachers should not be too definitely practical in aim. The student
should not be observing to find out how the good teacher does it, in order to accumulate a store of
methods by which he also may teach successfully. He should rather observe with reference to
seeing the interaction of mind, to see how teacher and pupils react upon each other—how mind
answers to mind. Observation should at first be conducted from the psychological rather than
from the “practical” standpoint. If the latter is emphasized before the student has an independent
command of the former, the principle of imitation is almost sure to play an exaggerated part in the
observer’s future teaching, and hence at the expense of personal insight and initiative. What the
student needs most at this stage of growth is ability to see what is going on in the minds of a
group of persons who are in intellectual contact with one another. He needs to learn to observe
psychologically—a very different thing from simply observing how a teacher gets “good results”
in presenting any particular subject.

It should go without saying that the student who has acquired power in psychological observa-
tion and interpretation may finally go on to observe more technical aspects of instruction, namely,
the various methods and instrumentalities used by a good teacher in giving instruction in any
subject. If properly prepared for, this need not tend to produce copiers, followers of tradition and
example. Such students will be able to translate the practical devices which are such an important
part of the equipment of a good teacher over into their psychological equivalents; to know not
merely as a matter of brute fact that they do work, but to know how and why they work. Thus he will be an independent judge and critic of their proper use and adaptation.

In the foregoing I have assumed that educational psychology is marked off from general psychology simply by the emphasis which it puts upon two factors. The first is the stress laid upon a certain end, namely, growth or development—with its counterparts, arrest and adaptation. The second is the importance attached to the social factor—to the mutual interaction of different minds with each other. It is, I think, strictly true that no educational procedure nor pedagogical maxim can be derived directly from pure psychological data. The psychological data taken without qualification (which is what I mean by their being pure) cover everything and anything that may take place in a mind. Mental arrest and decay occur according to psychological laws, just as surely as do development and progress.

We do not make practical maxims out of physics by telling persons to move according to laws of gravitation. If people move at all, they must move in accordance with the conditions stated by this law. Similarly, if mental operations take place at all, they must take place in accordance with the principles stated in correct psychological generalizations. It is superfluous and meaningless to attempt to turn these psychological principles directly into rules of teaching. But the person who knows the laws of mechanics knows the conditions of which he must take account when he wishes to reach a certain end. He knows that if he aims to build a bridge, he must build it in a certain way and of certain materials, or else he will not have a bridge, but a heap of rubbish. So in psychology. Given an end, say promotion of healthy growth, psychological observations and reflection put us in control of the conditions concerned in that growth. We know that if we are to get that end, we must do it in a certain way. It is the subordination of the psychological material to the problem of effecting growth and avoiding arrest and waste which constitutes a distinguishing mark of educational psychology.

I have spoken of the importance of the social factor as the other mark. I do not mean, of course, that general theoretical psychology ignores the existence and significance of the reaction of mind to mind—though it would be within bounds to say that till recently the social side was an unwritten chapter of psychology. I mean that considerations of the ways in which one mind responds to the stimuli which another mind is consciously or unconsciously furnishing possess a relative importance for the educator which they have not for the psychologist as such. From the teacher’s standpoint, it is not too much to say that every habit which a pupil exhibits is to be regarded as a reaction to stimuli which some persons or group of persons have presented to the child. It is not too much to say that the most important thing for the teacher to consider, as regards his present relations to his pupils, is the attitudes and habits which his own modes of being, saying, and doing are fostering or discouraging in them.

Now, if these two assumptions regarding educational psychology be granted, I think it will follow as a matter of course, that only by beginning with the values and laws contained in the student’s own experience of his own mental growth, and by proceeding gradually to facts connected with other persons of whom he can know little; and by proceeding still more gradually to the attempt actually to influence the mental operations of others, can educational theory be made most effective. Only in this way can the most essential trait of the mental habit of the teacher be secured—that habit which looks upon the internal, not upon the external; which sees that the important function of the teacher is direction of the mental movement of the student, and that the mental movement must be known before it can be directed.

II. I turn now to the side of subject-matter, or scholarship, with the hope of showing that here too the material, when properly presented, is not so merely theoretical, remote from the practical problems of teaching, as is sometimes supposed. I recall that once a graduate student in a university made inquiries among all the leading teachers in the institution with which he was connected as to whether they had received any professional training, whether they had taken courses in pedagogy. The inquirer threw the results, which were mostly negative, into the camp of
the local pedagogical club. Some may say that this proves nothing, because college teaching is proverbially poor, considered simply as teaching. Yet no one can deny that there is some good teaching, and some teaching of the very first order, done in colleges, and done by persons who have never had any instruction in either the theory or the practice of teaching.

This fact cannot be ignored any more than can the fact that there were good teachers before there was any such thing as pedagogy. Now, I am not arguing for not having pedagogical training—that is the last thing I want. But I claim the facts mentioned prove that scholarship per se may itself be a most effective tool for training and turning out good teachers. If it has accomplished so much when working unconsciously and without set intention, have we not good reason to believe that, when acquired in a training school for teachers—with the end of making teachers held definitely in view and with conscious reference to its relation to mental activity—it may prove a much more valuable pedagogical asset than we commonly consider it?

Scholastic knowledge is sometimes regarded as if it were something quite irrelevant to method. When this attitude is even unconsciously assumed, method becomes an external attachment to knowledge of subject-matter. It has to be elaborated and acquired in relative independence from subject-matter, and then applied.

Now the body of knowledge which constitutes the subject-matter of the student-teacher must, by the nature of the case, be organized subject-matter. It is not a miscellaneous heap of separate scraps. Even if (as in the case of history and literature), it be not technically termed “science,” it is none the less material which has been subjected to method—has been selected and arranged with reference to controlling intellectual principles. There is, therefore, method in subject-matter itself—method indeed of the highest order which the human mind has yet evolved, scientific method.

It cannot be too strongly emphasized that this scientific method is the method of mind itself. The classifications, interpretations, explanations, and generalizations which make subject-matter a branch of study do not lie externally in facts apart from mind. They reflect the attitudes and workings of mind in its endeavor to bring raw material of experience to a point where it at once satisfies and stimulates the needs of active thought. Such being the case, there is something wrong in the “academic” side of professional training, if by means of it the student does not constantly get object-lessons of the finest type in the kind of mental activity which characterizes mental growth and, hence, the educative process. It is necessary to recognize the importance for the teacher’s equipment of his own habituation to superior types of method of mental operation. The more a teacher in the future is likely to have to do with elementary teaching, the more, rather than the less, necessary is such exercise. Otherwise, the current traditions of elementary work with their tendency to talk and write down to the supposed intellectual level of children, will be likely to continue. Only a teacher thoroughly trained in the higher levels of intellectual method and who thus has constantly in his own mind a sense of what adequate and genuine intellectual activity means, will be likely, in deed, not in mere word, to respect the mental integrity and force of children.

Of course, this conception will be met by the argument that the scientific organization of subject-matter, which constitutes the academic studies of the student-teacher is upon such a radically different basis from that adapted to less mature students that too much preoccupation with scholarship of an advanced order is likely actually to get in the way of the teacher of children and youth. I do not suppose anybody would contend that teachers really can know more than is good for them, but it may reasonably be argued that continuous study of a specialized sort forms mental habits likely to throw the older student out of sympathy with the type of mental impulses and habits which are found in younger persons.

Right here, however, I think normal schools and teachers’ colleges have one of their greatest opportunities—an opportunity not merely as to teachers in training, but also for reforming methods of education in colleges and higher schools having nothing to do with the training of
teachers. It is the business of normal schools and collegiate schools of education to present subject-matter in science, in language, in literature and the arts, in such a way that the student both sees and feels that these studies are significant embodiments of mental operations. He should be led to realize that they are not products of technical methods, which have been developed for the sake of the specialized branches of knowledge in which they are used, but represent fundamental mental attitudes and operations—that, indeed, particular scientific methods and classifications simply express and illustrate in their most concrete form that of which simple and common modes of thought-activity are capable when they work under satisfactory conditions.

In a word, it is the business of the “academic” instruction of future teachers to carry back subject-matter to its common psychical roots. In so far as this is accomplished, the gap between the higher and the lower treatment of subject-matter, upon which the argument of the supposed objector depends, ceases to have the force which that argument assigns to it. This does not mean, of course, that exactly the same subject-matter, in the same mode of presentation, is suitable to a student in the elementary or high schools that is appropriate to the normal student. But it does mean that a mind which is habituated to viewing subject-matter from the standpoint of the function of that subject-matter in connection with mental responses, attitudes, and methods will be sensitive to signs of intellectual activity when exhibited in the child of four, or the youth of sixteen, and will be trained to a spontaneous and unconscious appreciation of the subject-matter which is fit to call out and direct mental activity.

We have here, I think, the explanation of the success of some teachers who violate every law known to and laid down by pedagogical science. They are themselves so full of the spirit of inquiry, so sensitive to every sign of its presence and absence, that no matter what they do, nor how they do it, they succeed in awakening and inspiring like alert and intense mental activity in those with whom they come in contact.

This is not a plea for the prevalence of these irregular, inchoate methods. But I feel that I may recur to my former remark: if some teachers, by sheer plentitude of knowledge, keep by instinct in touch with the mental activity of their pupils, and accomplish so much without, and even in spite of principles which are theoretically sound, then there must be in this same scholarship a tremendous resource when it is more consciously used—that is, employed in clear connection with psychological principles.

When I said above that schools for training teachers have here an opportunity to react favorably upon general education, I meant that no instruction in subject-matter (wherever it is given) is adequate if it leaves the student with just acquisition of certain information about external facts and laws, or even a certain facility in the intellectual manipulation of this material. It is the business of our higher schools in all lines, and not simply of our normal schools, to furnish the student with the realization that, after all, it is the human mind, trained to effective control of its natural attitudes, impulses, and responses, that is the significant thing in all science and history and art so far as these are formulated for purposes of study.

The present divorce between scholarship and method is as harmful upon one side as upon the other—as detrimental to the best interests of higher academic instruction as it is to the training of teachers. But the only way in which this divorce can be broken down is by so presenting all subject-matter, for whatever ultimate, practical, or professional purpose, that it shall be apprehended as an objective embodiment of methods of mind in its search for, and transactions with, the truth of things.

Upon the more practical side, this principle requires that, so far as students appropriate new subject-matter (thereby improving their own scholarship and realizing more consciously the nature of method), they should finally proceed to organize this same subject-matter with reference to its use in teaching others. The curriculum of the elementary and the high school constituting the “practice” or “model” school ought to stand in the closest and most organic relation to the
instruction in subject-matter which is given by the teachers of the professional school. If in any given school this is not the case, it is either because in the training class subject-matter is presented in an isolated way, instead of as a concrete expression of methods of mind, or else because the practice school is dominated by certain conventions and traditions regarding material and the methods of teaching it, and hence is not engaged in work of an adequate educational type.

As a matter of fact, as everybody knows, both of these causes contribute to the present state of things. On the one hand, inherited conditions impel the elementary school to a certain triviality and poverty of subject-matter, calling for mechanical drill, rather than for thought-activity, and the high school to a certain technical mastery of certain conventional culture subjects, taught as independent branches of the same tree of knowledge! On the other hand traditions of the different branches of science (the academic side of subject-matter) tend to subordinate the teaching in the normal school to the attainment of certain facilities, and the acquirement of certain information, both in greater or less isolation from their value as exciting and directing mental power.

The great need is convergence, concentration. Every step taken in the elementary and the high school toward intelligent introduction of more worthy and significant subject-matter, one requiring consequently for its assimilation thinking rather than "drill," must be met by a like advance step in which the mere isolated specialization of collegiate subject-matter is surrendered, and in which there is brought to conscious and interested attention its significance in expression of fundamental modes of mental activity—so fundamental as to be common to both the play of the mind upon the ordinary material of everyday experience and to the systematized material of the sciences.

III. As already suggested, this point requires that training students be exercised in making the connections between the course of study of the practice or model school, and the wider horizons of learning coming within their ken. But it is consecutive and systematic exercise in the consideration of the subject-matter of the elementary and high schools that is needed. The habit of making isolated and independent lesson plans for a few days' or weeks' instruction in a separate grade here or there not only does not answer this purpose, but is likely to be distinctly detrimental. Everything should be discouraged which tends to put the student in the attitude of snatching at the subject-matter which he is acquiring in order to see if by some hook or crook it may be made immediately available for a lesson in this or that grade. What is needed is the habit of viewing the entire curriculum as a continuous growth, reflecting the growth of mind itself. This in turn demands, so far as I can see, consecutive and longitudinal consideration of the curriculum of the elementary and high school rather than a cross-sectional view of it. The student should be led to see that the same subject-matter in geography, nature-study, or art develops not merely day to day in a given grade, but from year to year throughout the entire movement of the school; and he should realize this before he gets much encouragement in trying to adapt subject-matter in lesson plans for this or that isolated grade.

C. If we attempt to gather together the points which have been brought out, we should have a view of practice work something like the following—though I am afraid even this formulates a scheme with more appearance of rigidity than is desirable:

At first, the practice school would be used mainly for purposes of observation. This observation, moreover, would not be for the sake of seeing how good teachers teach, or for getting "points" which may be employed in one's own teaching, but to get material for psychological observation and reflection, and some conception of the educational movement of the school as a whole.

Secondly, there would then be more intimate introduction to the lives of the children and the work of the school through the use as assistants of such students as had already got psychological insight and a good working acquaintance with educational problems. Students at this stage would not undertake much direct teaching, but would make themselves useful in helping
the regular class instructor. There are multitudes of ways in which such help can be given and be of real help—that is, of use to the school, to the children, and not merely of putative value to the training student.\textsuperscript{6} Special attention to backward children, to children who have been out of school, assisting in the care of material, in forms of hand-work, suggest some of the avenues of approach.

This kind of practical experience enables, in the third place, the future teacher to make the transition from his more psychological and theoretical insight to the observation of the more technical points of class teaching and management. The informality, gradualness, and familiarity of the earlier contact tend to store the mind with material which is unconsciously assimilated and organized, and thus supplies a background for work involving greater responsibility.

As a counterpart of this work in assisting, such students might well at the same time be employed in the selection and arrangement of subject-matter, as indicated in the previous discussion. Such organization would at the outset have reference to at least a group of grades, emphasizing continuous and consecutive growth. Later it might, without danger of undue narrowness, concern itself with finding supplementary materials and problems bearing upon the work in which the student is giving assistance; might elaborate material which could be used to carry the work still farther, if it were desirable; or, in case of the more advanced students, to build up a scheme of possible alternative subjects for lessons and studies.

Fourthly, as fast as students are prepared through their work of assisting for more responsible work, they could be given actual teaching to do. Upon the basis that the previous preparation has been adequate in subject-matter, in educational theory, and in the kind of observation and practice already discussed, such practice-teachers should be given the maximum amount of liberty possible. They should not be too closely supervised, nor too minutely and immediately criticised upon either the matter or the method of their teaching. Students should be given to understand that they not only are permitted to act upon their own intellectual initiative, but that they are expected to do so, and that their ability to take hold of situations for themselves would be a more important factor in judging them than their following any particular set method or scheme.

Of course, there should be critical discussion with persons more expert of the work done, and of the educational results obtained. But sufficient time should be permitted to allow the practice-teacher to recover from the shocks incident to the newness of the situation, and also to get enough experience to make him capable of seeing the fundamental bearings of criticism upon work done. Moreover, the work of the expert or supervisor should be directed to getting the student to judge his own work critically, to find out for himself in what respects he has succeeded and in what failed, and to find the probable reasons for both failure and success, rather than to criticising him too definitely and specifically upon special features of his work.

It ought to go without saying (unfortunately, it does not in all cases) that criticism should be directed to making the professional student thoughtful about his work in the light of principles, rather than to induce in him a recognition that certain special methods are good, and certain other special methods bad. At all events, no greater travesty of real intellectual criticism can be given than to set a student to teaching a brief number of lessons, have him under inspection in practically all the time of every lesson, and then criticise him almost, if not quite, at the very end of each lesson, upon the particular way in which that particular lesson has been taught, pointing out elements of failure and of success. Such methods of criticism may be adapted to giving a training-teacher command of some of the knacks and tools of the trade, but are not calculated to develop a thoughtful and independent teacher.

Moreover, while such teaching (as already indicated) should be extensive or continuous enough to give the student time to become at home and to get a body of funded experience, it ought to be intensive in purpose rather than spread out miscellaneous. It is much more important for the teacher to assume responsibility for the consecutive development of some one topic, to get a feeling for the movement of that subject, than it is to teach a certain number (necessarily
smaller in range) of lessons in a larger number of subjects. What we want, in other words, is not so much technical skill, as a realizing sense in the teacher of what the educational development of a subject means, and, in some typical case, command of a method of control, which will then serve as a standard for self-judgment in other cases.

Fifthly, if the practical conditions permit—if, that is to say, the time of the training course is sufficiently long, if the practice schools are sufficiently large to furnish the required number of children, and to afford actual demand for the work to be done—students who have gone through the stages already referred to should be ready for work of the distinctly apprenticeship type.

Nothing that I have said heretofore is to be understood as ruling out practice teaching which is designed to give an individual mastery of the actual technique of teaching and management, provided school conditions permit it in reality and not merely in external form—provided, that is, the student has gone through a training in educational theory and history, in subject-matter, in observation, and in practice work of the laboratory type, before entering upon the latter. The teacher must acquire his technique some time or other; and if conditions are favorable, there are some advantages in having this acquisition take place in cadetting or in something of that kind. By means of this probation, persons who are unfit for teaching may be detected and eliminated more quickly than might otherwise be the case and before their cases have become institutionalized.

Even in this distinctly apprenticeship stage, however, it is still important that the student should be given as much responsibility and initiative as he is capable of taking, and hence that supervision should not be too unremitting and intimate, and criticism not at too short range or too detailed. The advantage of this intermediate probationary period does not reside in the fact that thereby supervisory officers may turn out teachers who will perpetuate their own notions and methods, but in the inspiration and enlightenment that come through prolonged contact with mature and sympathetic persons. If the conditions in the public schools were just what they ought to be, if all superintendents and principals had the knowledge and the wisdom which they should have, and if they had time and opportunity to utilize their knowledge and their wisdom in connection with the development of the younger teachers who come to them, the value of this apprenticeship period would be reduced, I think, very largely to its serving to catch in time and to exclude persons unfitted for teaching.

In conclusion, I may say that I do not believe that the principles presented in this paper call for anything utopian. The present movement in normal schools for improvement of range and quality of subject-matter is steady and irresistible. All the better classes of normal schools are already, in effect, what are termed “junior colleges.” That is, they give two years’ work which is almost, and in many cases quite, of regular college grade. More and more, their instructors are persons who have had the same kind of scholarly training that is expected of teachers in colleges. Many of these institutions are already of higher grade than this; and the next decade will certainly see a marked tendency on the part of many normal schools to claim the right to give regular collegiate bachelor degrees.

The type of scholarship contemplated in this paper is thus practically assured for the near future. If two other factors cooperate with this, there is no reason why the conception of relation of theory and practice here presented should not be carried out. The second necessary factor is that the elementary and high schools, which serve as schools of observation and practice, should represent an advanced type of education properly corresponding to the instruction in academic subject-matter and in educational theory given to the training classes. The third necessity is that work in psychology and educational theory make concrete and vital the connection between the normal instruction in subject-matter and the work of the elementary and high schools.

If it should prove impracticable to realize the conception herein set forth, it will not be, I think, because of any impossibility resident in the outward conditions, but because those in authority, both within and without the schools, believe that the true function of training schools is just to
meet the needs of which people are already conscious. In this case, of course, training schools will be conducted simply with reference to perpetuating current types of educational practice, with simply incidental improvement in details. The underlying assumption of this paper is, accordingly, that training schools for teachers do not perform their full duty in accepting and conforming to present educational standards, but that educational leadership is an indispensable part of their office. The thing needful is improvement of education, not simply by turning out teachers who can do better the things that are now necessary to do, but rather by changing the conception of what constitutes education.

NOTES

1 This paper is to be taken as representing the views of the writer, rather than those of any particular institution in an official way; for the writer thought it better to discuss certain principles that seem to him fundamental, rather than to define a system of procedure.
2 There is where the plea for “adult” psychology has force. The person who does not know himself is not likely to know others. The adult psychology ought, however, to be just as genetic as that of childhood.
3 It may avoid misapprehension if I repeat the word experience. It is not a metaphysical introspection that I have in mind, but the process of turning back upon one’s own experiences, and turning them over to see how they were developed, what helped and hindered, the stimuli and the inhibitions both within and without the organism.
4 Professor Ella F. Young’s Scientific Method in Education (University of Chicago Decennial Publications) is a noteworthy development of this conception, to which I am much indebted.
5 It is hardly necessary to refer to Dr. Harris’s continued contention that normal training should give a higher view or synthesis of even the most elementary subjects.
6 This question of some real need in the practice school itself for the work done is very important in its moral influence and in assimilating the conditions of “practice work” to those of real teaching.
6.2 Growth of teachers in professional maturity

Lucy Sprague Mitchell

An old professor once said that the proof of the pudding is not in the eating but comes several hours later. This holds true of more things than puddings! The results of an educational experiment such as the Bank Street Workshops do not show until several years later. It takes time to do what we were attempting—to explore what experiences, approaches, and techniques in an inservice situation are best adapted to further teachers’ growth toward professional maturity. Both we and the teachers had to learn on the job. Growth is a slow process. One cannot expect quick results. In the second place, when one is immersed in the daily exigencies and details of a job, one cannot get far enough away from them to see things that are happening slowly. If one does not see a child for a number of years, one is actually startled at his growth—far more his parents, who have seen him daily. So is it with a long-term experiment. It is only later when one can study the day-by-day records with a detached attitude that one can get a total picture. That is the reason for keeping records—to have something more reliable than memory as a basis for an analysis. When records of several years are put together they form a kind of moving picture of what has happened.

In Part II we told the story of our Workshops largely as that of technicians. There we made a report based on the day-to-day records of what happened in six years. In such a report one can hardly see the forest for the trees. Now, in Part III, we shall turn from detailed reporting to analysis, from what the Workshops did to what we and the teachers learned through the doing.

We begin with an analysis of the growth of the teachers in understanding and enjoyment of their new job, which, as has been repeatedly said, was the central aim of our Workshop experiment. Throughout the experiment we measured the success or failure of our Workshop techniques in terms of their contribution to the teachers’ professional growth. We shall go back to the initial attitudes of the teachers toward their job and what they wanted from the Workshop and analyze what kinds of situations hinder or aid the growth of teachers, and the stages of growth by which teachers progress toward professional maturity. This will take us rapidly over some of the same ground covered in Part II, since our analysis is necessarily based on the record of what happened in the Workshops.

INITIAL ATTITUDES TOWARD THEIR JOB AND WORKSHOP

Obviously, teachers cannot be lumped together as people with similar characteristics and personalities or attitudes toward life any more than can parents or miners or cooks or lawyers. What any of these groups have in common is not personality characteristics but a kind of work. When we come to analyze the growth of teachers we shall concentrate on professional thinking and attitudes and largely ignore the wide variations in personality, background, interests, and prejudices which they bring to the teaching job, though all these factors affect their professional
growth. If we find a group of highly diversified personalities holding similar attitudes toward their work, we shall examine the conditions under which this work is carried on and ask how far these conditions explain the attitudes common to the group.

So we begin by recalling the initial attitudes of the Workshop teachers toward their job as shown by what they wanted from a Workshop. The situation in the New York schools when we began our Workshop was typical, we think, of the situations prevailing in many, perhaps most, of our schools throughout the country. The thinking and attitudes about children and curriculum to be planned for them were in a state of transition. The “new curriculum” embodying the new thinking and attitudes had been given to the teachers but in practice had not genuinely superseded the old curriculum. In varying degrees the teachers clung to the familiar old curriculum (which to them meant largely subject matter) which had been set up over twenty years before under twenty or more separate courses of study. Within this old framework they were trying conscientiously to carry out the newer methods of teaching which, for a number of years, they had been instructed to use. A common complaint of the teachers was that, though they were willing to follow the new curriculum, they were handicapped by the conditions under which they worked—large classes, lack of space in the classrooms, old equipment, etc. They devoted “periods” to activity programs, units, trips, research, conferences, and “show and tell periods” in which children “expressed themselves,” but for the most part these periods were thought of as extras, as episodes which interrupted the real work, “the desirable information” contained in the old syllabus.

Many teachers still depended largely upon the traditional source of “desirable information”—that is, textbooks which contained facts to be memorized. They were not tied to a single textbook as they were in the early traditional schools; but most of the added books were still heavily weighted with factual information—a variety of textbooks, encyclopedias, etc. For the most part, “research” meant reading one of these books. There was little use of genuine source material for research—pictures, maps, written materials which children were called upon to interpret, which challenged them to think out relationships for themselves. Few teachers thought of the functioning world outside of the classrooms, the world in which their children lived, as a laboratory where children could have firsthand experiences, carry on investigations on a young level under teacher guidance, which would start new interests and give meaning to factual information contained in books.

The teachers had also been given instructions in regard to their attitude toward children and methods of “handling” them. Here, the teachers conscientiously tried to follow out these instructions. In order to let the children freely express themselves in conferences, many teachers simply handed over the situation to the children and stepped out of any participation in or responsibility for these “free” periods. The children were both young and inexperienced in handling such responsibility. Without teacher guidance, they got nowhere and the listening children were simply bored. In subtler ways the new instructions concerning the “atmosphere” of classrooms brought difficulties to many teachers, in an attempt to let children be “free,” they relaxed the old repressive kind of discipline before building up self-discipline within group or an individual child. They confused freedom with license, with disastrous results for both themselves and the children.

In this situation the teachers were practically unanimous in what they wanted from a Workshop. They wanted to be shown how to conduct the new teaching techniques they had been instructed to use, not why. Their primary interest was not to understand educational and psychological basis of the new curriculum better. They stated emphatically that they wanted “no theory” from us- that they had had enough theoretical talk. They wanted “practical help” in carrying out instructions. These teachers obviously felt insecure as technicians in their “new job.” This was only natural in this transition stage from old to new curriculum and was typical of teachers wherever school systems were trying to introduce new thinking and attitudes. For, broadly speaking, the experienced teachers nearly everywhere have been trained with major emphasis on subject
methodology and have taught under a system which has upheld this traditional approach. These experienced teachers—who had self-confidence when officially supported by courses of study which gave detailed content to be covered in each term, by textbooks with recitation, by disciplinary punishment, gold star rewards—lost their self-confidence when their instructions became less rigid and less detailed. They attempted conscientiously to carry out whatever new instructions were given to them in the way of new techniques—units, trips, conferences, research, children committees, etc. But as a whole, these teachers felt little responsibility for studying their children and for planning experiences for them on the basis of such study. In some schools the teachers were told to be experimental, but few of them were or wanted to be.

In brief, the teachers’ initial attitude toward their job was to follow instructions, to put new teaching techniques into practice without much responsibility for understanding the psychological and educational thinking that lay behind these techniques. What had brought about this attitude toward their job? It is important to try to answer this question. For such an attitude toward their job must profoundly affect the growth toward professional maturity of teachers everywhere who have a similar attitude. It is important to know whether psychological conditions under which the teachers carried on their job might explain the common attitude toward their job of a group of highly diversified personalities.

PSYCHOLOGICAL EFFECT OF ADMINISTRATIVE SYSTEM UPON TEACHERS’ ATTITUDES

In telling the story of the development of our public school Workshops in Part II, we described the stage set of that six-year experiment with one important omission—the psychological effect upon teachers of the vast administrative system under which they worked and in which most of them had all their teaching experience. A large proportion of the teachers of our country’s children work under somewhat similar systems. So it seems well to attempt some analysis of the nature of administrative systems and how such systems psychologically condition the attitude of teachers toward their job and consequently their growth toward understanding and enjoyment in their new job.

A big school system is organized as an administrative hierarchy with responsibilities for decisions (which means instructions given or permission granted) belonging to a graded series of officials. At the top is the Superintendent of Schools; at the bottom are the teachers, whose job is directly with children, for whom the whole system has come into being. Each successive step up the graded responsibilities is one more step removed from children. A good principal knows the children in his school, but not in the intimate way the teachers do. He deals more with teachers than with children. A good district superintendent knows the children and the teachers in his district only as he sees them in occasional visits to the classrooms. He deals more with principals than with teachers and more with teachers than with children. Step by step up the administrative ladder, officials acquire wider and wider responsibilities and power and become more separated from children and their teachers. And promotion up the rungs of the ladder means increase in salary, which inevitably enhances the higher positions and stimulates the desire for promotion. Such is the nature of this hierarchical type of organization, whether in a school system, a government, an army, or anywhere else.

What psychological effect has this type of administrative organization upon the members who compose it? Since wider power and higher salary depend upon promotion to the next rung of the ladder, it tends to turn the eyes of the members at each level upwards to the occupants on the upper levels, to make them look to their immediate “superior” for instructions, to seek the superior’s approval—all of which tends to mean following out his instructions, his thinking and planning, rather than concentrating their thinking and planning upon the responsibilities at their
own level and acting according to their own judgments based upon their own experiences. At its worst, an administrative hierarchy can draw the attention and energies of an ambitious member at any level away from developing his immediate job, and make him an authoritarian in respect to those on the level below him, perhaps to offset the power exercised over him by his immediate superior. An ambitious teacher who is at the lowest level of administrative authority may have his eyes drawn from children to promotion; he, too, may become an authoritarian in his classroom to offset emotionally the power the principal has over him. How to conduct the complicated machinery of a vast school system without the evils of minimizing the importance of the job at each level and without breeding the authoritarian attitude is one of the major problems of public education.

At its best, any administrative ladder has to some extent a psychological effect upon all teachers—not merely upon the comparatively few who are more interested in their own promotion than anything else. The very nature of graded responsibilities (leaving out the salary aspect) is to make teachers who are on the lowest level look to their immediate superior, the principal, for instructions and to conceive of their job as following out his instructions and the instructions issued by those faraway supreme powers, the Board of Education and the Board of Superintendents. Their whole experience within the administrative setup of a big school system has been away from their taking the responsibility for planning individually for their particular children, away from experimentation and initiative in their classrooms, away from trusting their own judgments based on their own experiences, away from taking part or even following educational efforts which do not affect them personally—in short, away from taking their teaching job as a profession. It is an anomaly inherent in this form of administration that the teachers, who are on the lowest level both in responsibility for educational decisions and in salary, are the ones who really control the school lives of the children for whom, presumably, the whole towering system has been erected. It was striking that, as the teachers relaxed in the informal atmosphere of the Workshop, they again and again expressed their sense of this anomaly. They posed this question as one of their greatest problems—How could they take responsibilities for educational thinking within their classrooms though they still remained on the lowest level as far as general decisions for educational thinking in the system are concerned?

It may be that all of this is but a reflection of the total society in which our public school system evolved—a time when the hierarchical ladder prevailed in business, in family, in social organizations. To succeed meant in all walks of life rising step by step, away from the actual work of the job nearer and nearer to management—to giving instead of taking orders. All institutions shifting from the old hierarchical form of structure to one more consistent with democratic ideals find difficulty in the transition. And this on every rung of the ladder, those on top trying to develop a more liberal approach as well as those below trying to use a new freedom. Historic lags are characteristic of all institutions in transition. It is all a part of the evolution of democracy.

STAGES OF TEACHERS’ PROFESSIONAL GROWTH

As we came to know the teachers, we became sure that their early concentration of their interest on learning—teaching new techniques grew out of their attitude toward their job—an attitude which had been built up within an administrative ladder system in which they had been expected to follow instruction from “superior” officials rather than to think through educational and psychological problems for themselves. Their new job asked many new things of them besides using new teaching techniques. It asked them to study their children’s needs and interests. It asked them to be flexible, to adapt their programs to their children. It asked them to take responsibility for planning, to be experimental. But psychologically they had been conditioned by what had been asked of them under a hierarchical ladder system in which they stood on the lowest rung.
Their role had been to follow instructions handed down from above. No wonder that they did not trust themselves to take on new kinds of responsibilities and initiative, to be experimental. No wonder their anxieties centered upon learning how with only secondary interest in learning why.

First stage: self-confidence in thinking, planning, and experimenting

This, then, was where the Workshop began. The teachers, for all their differences in personality, in background content, were impatient of talk about what children are like and how fit a curriculum to children’s needs; they said such basic concepts were “mere theory” and of “no practical use” to them; they were unanimous in wanting from us practical help—to be told or shown how to handle “the activity program” or how to organize and conduct a “unit.” Since we believed teachers, like everyone else, learn better by experience than by words, we began what they called “demonstration teaching” of children in the classrooms, followed in our Workshop meetings by discussions of the children’s responses. We planned and took trips with a teacher and her children; we helped to get dramatic play started, or to organize and original play, or to make a map or a mural; we conducted a science experiment, and led follow-up discussions with the children.

After such demonstration teaching, the teachers tended to repeat what we done rather than to work out new experiences for the children adapted to a new situation. A few illustrations: After a staff member had planned and taken a trip a teacher and her children, a teacher repeated the same trip with her next group of children though a different trip would have contributed more to the current study. Teachers continued to use the source material we had brought rather than hunt for new materials themselves. After a staff member had helped a class of sixth-grade children to organize an original play by starting them off on writing jingles for each step in the process of making a woolen coat, from the sheep to buying the coat in a store, the teacher repeated this same pattern in the plays she later helped the children to write. That is, the teachers followed rather than taking initiative and experimenting along new lines. We were convinced that this pattern of following was not due to lack of originality or ability. Nor did we think the teachers were particularly resistant to a new way of teaching. Rather, they lacked self-confidence in what was genuinely a new job. We felt their pattern of following was a holdover of attitudes built up by their old job, in which they had been expected to follow in detail the instructions handed out to them. So long as they held to this old pattern, they could not throw themselves wholeheartedly into what was genuinely a new job. But to break this pattern they needed a degree of self-confidence, and that required time. The assurance that we were not supervisors trying to rate them was accepted only slowly. When it was finally accepted, they became less afraid of failure. The first stage in their growth was when they acquired enough self-confidence to experiment, to try out something new and not be unduly upset if their first trial was not altogether successful. Only then did tension begin to give way to satisfaction in this new way of teaching.

Naturally, it took some teachers longer than others to reach this first stage of self-confidence. We continued to give concrete suggestions and to encourage any attempt at independent planning until a teacher felt secure enough to use us as advisers rather than as guides to be followed.

Second stage: desire to acquire background content

At first we supplied the background content and source material necessary for any particular project or unit. Each of us arrived at school staggering under some load. We brought relevant books for both the children and the teachers. We brought pictures from our Bank Street files—even enormous graphic relief maps difficult to manipulate in the subway. We also brought some educational materials and tools such as simple science equipment and our Bank Street tubs of
plasticine when the teachers modeled maps. In all our informal discussions with the children or at Workshop meetings, we naturally drew upon the background content which we had accumulated through years of teaching children and teachers. Much of it was new to the teachers. Most of them used our source materials and background content eagerly when saw how interested their children were and how children began to observe new things and ask questions which showed genuine intellectual curiosity.

By the end of our first Workshop year, a common remark was, “We don’t know enough to teach this way—we haven’t the background content.” The group, as a whole, asked to devote considerable time the following year to talks on straight background content. Many asked for a list of readings for the summer. As a group they decided to work on gathering such material for a school source material library. Here was a big step forward in the teachers’ growth—a step which meant an appreciation of how the use of all sorts of sources could enrich the children’s curriculum experiences. It meant more than that, too. Eventually it meant an acceptance of more afterschool work as a part of their job. It meant a sharing of their experiences and problems and a sharing among themselves of precious “private” stores of pictures and other source materials. It meant an extension of their interest and their sense of responsibility from their own classroom to the school as a whole.

Third stage: growth of the concept of curriculum building

The teachers’ understanding and interest in their new job broadened gradually along two lines—subject matter and child development—until they finally merged into the concept of curriculum building.

Their growth in thinking about child development had gone through several stages. At first their interest was largely limited to disturbed children. Nearly every teacher had some children whose behavior showed maladjustment, and some teachers had classes composed entirely of such children. The teachers’ initial approach to child psychology was in terms of the troublesome problems they had to handle in their own classrooms. Many of the teachers began by rejecting children with behavior problems. “You can’t do anything with such children.” “You can’t change their homes, so why try to do anything?” “They oughtn’t to be in school anyway.” This attitude of rejection gradually grew into an eagerness to understand why these children were so disturbed and disturbing, a challenging of a quick judgment that nothing could be done for them in school. Of course, a number of children were too unstable to be in school. But more and more, the teachers wished to give understanding help before saying, “They oughtn’t to be in school.”

From this limited interest in disturbed children the interest of most of the teachers eventually broadened until it included the total growth of all children. They came to recognize that all children have emotional needs which teachers must meet; also, that a child’s ability to learn is closely tied up with a satisfying life. They began to question some of the old techniques of human relationships such as praise cards and gold stars. What did such rewards do to those unsuccessful in this competition? To those who succeeded? Did such rewards split the group into rival camps? Did they turn attention to achievements rather than to interest? Most of the teachers came to feel such rewards were harmful, that children were as genuinely interested in co-operation, group undertakings, as they were in competition. They told the principal how they felt and he accepted their point of view.

This growth in understanding children was brought about in a large measure by the Workshop discussions of actual children in this school—children these teachers were teaching—rather than of “the child” in general. The Bank Street psychologist observed the children in their classrooms and then discussed them in the Workshop. The principal had asked each teacher to make a case study of one child. Since most of these case studies were of disturbed children, the psychologist asked each teacher to make at least one study of a child the teacher felt was growing
Discussion of these case studies of their own children helped the teachers to understand the emotional needs of all children and the special needs at different stages of maturity as a basis of teacher-child relationships as well as the other human relationships in the home and with other children. Understanding children’s emotional needs made a marked difference in the atmosphere of the classrooms of many teachers.

Another closely related aspect of child development was how children learn at various stages in their process of growing up. Such words as “children’s interest drives,” “direct experiences,” “maturity levels,” passed from the realm of theory into the realm of practical curriculum planning. Understanding how children learn had direct bearing upon teaching techniques. The teachers’ interest in how to acquire skill in the new techniques broadened to why these techniques helped children to healthy all-around growth.

The teachers began by thinking of curriculum content as a series of separate courses of study and separate units. From this, bit by bit, they grew to think of a total program for their own children, a year’s program built up of progressive experiences and activities centered around basic relationships in various kinds of information that the children were gathering. When the teachers began to reach this point we suggested that the Workshop plan curriculum materials in social studies for the whole school system. The working out of this curriculum revealed a startling growth in the teachers whose interests only a year and a half before had been largely limited to the acquisition of new teaching techniques. Not only did they now think clearly and constructively about progressive steps in the total curriculum subject matter in social studies which children from kindergarten through sixth grade were ready to take: they extended their thinking to the children in the whole school system. That is, they did not want to do something for just their one school, though the Workshop had received permission to work out a fairly independent experimental curriculum. They distinctly wished to work with in the prescribed framework of the official curriculum. But within this official framework they wished to experiment, to find out how to interpret the prescribed curriculum content in ways that were best for children’s growth.

At this point, they were actually combining child development with curriculum content. Children’s needs—physical, intellectual, and emotional—became a basis not only for teaching techniques but for selection of subject matter as well. When the two basic concepts—child development and fitting the curriculum to the child—became thus closely interrelated, the teachers were ready to build a curriculum. The social studies curriculum which the Workshop wrote (teachers, administration, and Bank Street staff) was based on the two fundamental concepts—what children are like and what subject matter, experiences, and activities best further their growth. These were exactly the basic concepts which at the beginning of our Workshop the teachers had said were “mere theory” and “of no practical use” to them. That the teachers were able so quickly to understand and apply these concepts shows, we think, that as a group they were learners. And what better can be said of a grownup than that he is still a learner?

Fourth stage: relating their job to the world outside the school

As their own jobs became more creative, we thought we noticed that the teachers were keeping more closely in touch with educational thinking and happenings elsewhere. Current books and magazine articles were constantly recommended by teachers at our meetings, as were interesting exhibits and lectures. We thought this indicated that the teachers felt more closely identified with the broad aspects of education everywhere.

As the teachers became more responsible for building their social studies curriculum, we heard more and more talk about national and world issues. We are in no position to judge whether their social thinking had been stimulated, for we had not known them in their lives outside the school. But this we think we can say: the social problems of the world had become more related to their job as teachers and they shared their thinking both as adults and as professional teachers. The
suggestion that we ask someone to talk at a Workshop meeting about intercultural relations came from the teachers. One such meeting considered intercultural relations from the point of view of teaching techniques at various maturity levels. Another was frankly a thrashing out of points of view about the One-World concept on an adult level. We thought it significant that the teachers felt a Workshop for teachers in school was a suitable place for such discussions. We are reasonably sure that they would not have felt so at the beginning of our Workshop experiment.

TEACHERS DEVELOP A PROFESSIONAL ATTITUDE

All these growths, which we have somewhat arbitrarily enumerated as stages though many took place simultaneously, worked toward a professional attitude. Their attitude, their conception of their job, certainly expanded. And not merely in the kinds of work which, as we have indicated, they undertook in order to be better teachers. The most refreshing aspect of the growth of teachers as we watched it was subtle yet evident. There was an atmosphere of stimulation. Their new job was a challenge—not a frightening chore. Every Workshop teacher we met was bubbling over with some tale of “what her children had done.” These teachers, as we have said, had a deep interest in their children. When they saw their children taking on new interests, new zest for observing and finding out, new habits of tackling a problem by thinking out relationships, new ways of expressing their thinking and feelings, the teachers themselves became excited. It worked, this new curriculum! They became inventive, experimental!—and industrious, too. For this new way of teaching means hard work. The lazy, the indifferent will never teach this way except in superficial forms, but they are a small proportion of the teachers. Most of them got deep satisfaction in having a creative job. For that is exactly what their new job is. Creative jobs are always hard work, yes. But they are fun too.

We believe that only a negligible percentage of the teachers who have experienced creative teaching would wish to give it up. As they grow in creative power in their classrooms, they are more aware of and impatient at the practical handicaps under which their work is done and which are not inherent in this way of teaching—poor equipment, little space, large groups. Any school system that really wishes its teachers to do a creative job must implement its new curriculum. Any community that wishes its children to be taught by enthusiastic, creative teachers must insist that unnecessary handicaps be done away with. It may be that teachers themselves will become a force in bringing about clearer community thinking which will demand better working conditions for children and their teachers in our school. It may be that the teachers, once they are released from the psychological handicaps of authoritarian supervision to creative teaching, will become our educational leaders. They are closest to our children in their school lives. Is it too much to ask that we should look to them for educational guidance?
6.3 The nature of expertise in teaching

David C. Berliner

There are many reasons for studying expertise. For one, it is an interesting topic, and that alone is sufficient to promote a line of research. Expert mnemonists, chess players, taxi drivers, or mathematicians fascinate us, as idiot savants and geniuses do. Such individuals are rare, and their abilities seem mysterious to those of us who do not attain their levels of competence. In addition, the study of the perception and problem solving of experts sometimes provides insight into the cognitive processes and kinds of knowledge that they use, and these often differ substantially from the processes and knowledge base that are used by novices. Such information helps psychologists to understand more about the organization of memory, the way reasoning in a particular domain occurs, and the way judgments are made. This kind of knowledge can have practical benefits: it can be used to provide the scaffolding for the instruction of novices, to help them attain a greater degree of competence, though perhaps not expertise. Expertise, it should be remembered, is a characteristic that is ordinarily developed only after lengthy experience. It is descriptive of a level of performance ordinarily attained by only a small percentage of those who are competent at a task.

There are also other reasons for studying expertise in the area of teaching. With increased public criticism of teachers and schools, it has been a source of pride for teachers to learn that within the profession are individuals who resemble experts in other fields—bridge players, chess players, physicists, radiologists, and so forth (see Glaser, 1987; Chi et al., 1988). In addition, information about pedagogical expertise can help policy makers concerned about teacher testing, merit pay, career ladders, and alternative certification programs, all of which require an understanding of the kinds of performance that characterize experts and novices (Berliner, 1989).

An additional reason for pursuing the study of expertise among teachers is to make clear that there are forms of pedagogical knowledge that are quite sophisticated and complex and take years to learn. Pedagogical knowledge—knowledge of organization and management of classrooms, of motivation, teaching methods, discipline, and individual differences among students—is not generally valued by the public. Virtually anyone who has ever raised a child or trained a dog thinks that teaching is easy. Such people have not had to work in public school classrooms, where high levels of managerial, organizational, and interpersonal social skills are required merely to be a competent provider of instruction for twenty-five or thirty distinctly different individuals. What studies of expertise in the pedagogical domain seek is a greater understanding of the sophisticated forms of pedagogical knowledge used by expert teachers to accomplish instructional goals in the complex social environment called the public school classroom.

Because studying expertise is interesting, because it enables us to learn more about cognition, because it builds morale, and because there is a lack of understanding of the complexity of pedagogical knowledge, a number of studies have been undertaken to examine expert knowledge in the pedagogical domain. Of primary interest have been studies about the differences
between expert and novice teachers that affect instruction and achievement. Most of these studies have been concerned with teacher effectiveness, with focus on how these teachers might differ with regard to responsible teaching. This chapter attempts to change that by offering a selective review of some characteristics of expert pedagogues that highlight aspects of the literature that reflect on responsible teaching as well as effective teaching. This review is organized around seven propositions about expert and novice teachers for which empirical data exist.

**PROPOSITIONS**

**Proposition one: experts excel mainly in their own domains and in particular contexts**

The obvious reasons, Chi et al. (1988) state, that experts excel primarily in single domains, is that experts have a great deal more experience, probably reflected-on experience, in some domains than in others. Expert radiologists surveyed in studies by Lesgold and others (1988) were estimated to be looking at their one-hundred-thousandth x-ray. The chess experts studied in deGroot's (1965) seminal work and in other research (Newell and Simon, 1972; Chase and Simon, 1973) have been estimated to have spent ten to twenty thousand hours staring at chess positions. A perspective on this is offered by Posner (1988, p. xxxi): "a student who spends 40 hours a week for 33 weeks spends 1,320 hours studying. Imagine spending more than ten years in college studying one subject, chess, and you get some appreciation of the time commitment of master level players . . . It is reasonable to assume a chess master can recognize 50,000 different configurations of chess, not too far different from the number of different words an English reader may be able to recognize."

With lengthy time commitments necessary to become expert in complex areas of human functioning, it is no wonder that individuals generally excel in only a single area. In the study of teachers, we also note that time and experience play an important role in the development of expertise. On the basis of fragmentary evidence and anecdotal reports, some scholars propose that teachers do not hit their peak until they have at least five years of on-the-job experience. The expert teacher with ten years of experience has spent a minimum of ten thousand hours in classrooms as a teacher, preceded by at least fifteen thousand hours as a student. While not all such experienced teachers are experts, there are not likely to be many expert pedagogues who achieve their status without extensive classroom experience.

It is also likely that the domain-specific knowledge that is acquired through this experience is quite contextualized. For example, in one of our research studies, experts, advanced beginners, and novices were asked to teach a thirty-minute lesson on probability to a group of high school students (Berliner and others, 1988). While they taught the lesson, they were videotaped, and after the lesson, during stimulated recall, they were asked to tell us about their thinking and to justify their actions during teaching. The interesting thing about this study was the incredible level of anger that we triggered among all the expert teachers. We had assumed that they would breeze through the teaching task and that we would use their performance to assess the lesser skills to be shown by advanced beginners and novices. While the experts did, in fact, show more skills in a number of ways (Clarridge, 1988), all of them were angry about having to participate in the task. One of them walked out on the study, while another broke down and cried in the middle of it.

The reason for the teachers’ anger was that we had moved them from their classrooms to a laboratory situation, and they did not feel that they could perform well under such conditions. We had allocated thirty minutes for planning, enough for the advanced beginners and the novices to feel comfortable, but the experts claimed that they needed more time—from three hours to as
much as three weeks. From our interviews, we came to understand that experts rarely enter their classrooms without having taken all the time they need to thoroughly understand the content that they will teach and planning one or more activities to teach it. In addition, they did not know the students in this study.

Our interviews revealed that expert teachers’ expertise depends in part on knowing their students in three ways: (1) They know the cognitive abilities of the students they teach, and this helps them to determine the level at which to teach. (2) They know their students personally, and this allows for personal rather than bureaucratic and informal mechanisms of control to be used in teaching. (3) They have a reputation with their students. In the teachers’ own schools, their students knew that they were experts and had certain expectations about what their teaching would be like. These teachers had always had students who expected to be well taught and to learn a great deal, even if they were pushed to their intellectual limits. When they faced a group of strangers, none of these three aspects of “knowing the students” was present, and the teachers felt that they suffered from that. In addition, all the experts commented on the problems created by their inability to use routines, a basic part of any expert’s performance (Bloom, 1985; Leinhardt and Greeno, 1986; Berliner, 1987). By taking them out of their classrooms, we had taken away the context in which these expert pedagogues excel.

There are aspects of this study revealing concern for responsible teaching that were not made evident in the primary analyses of the data. The first of these is the experts’ demand for planning time sufficient for the instructional task. This concern need not just be thought of as a way for the experts to ensure more effective instruction. Another interpretation also fits these data. Compared to novices and advanced beginners, expert teachers appear to have such high self-respect and respect for their students that they consider it markedly unprofessional to show up in class without having mastered their material completely. They seem to feel that they owe that to their students and are embarrassed when they cannot fulfill that part of their social contract with them. Participation in this study may have been perceived as requiring the breaking of a moral obligation, and that may account for some of the unexpectedly high level of anger that was expressed. A second ethical concern among the experts was seen in their need to have one or more activities planned before initiating instruction. We think that this is because most of them strive for an instructional setting that is not lecture-oriented and teacher-dominated, which does not require a lot of planning time, but prefer instead, a more indirect method of teaching. This was less true of the novices and advanced beginners, who seemed much more direct in their instruction.

A third noteworthy aspect of the experts’ behavior was their concern with knowing more about their students. The interviews revealed that this was required in order to accommodate instruction to their students’ needs, a form of consideration not especially noted among the novice and advanced beginning teachers in this sample. Perhaps the most interesting aspect of the experts’ behavior was their perception that their lack of personal knowledge about the students that they had to teach required them to use bureaucratic rather than informal mechanisms to control student behavior. All but one of the experts seemed upset by that. The task seemed to call for them to adopt more authoritarian roles than they had become accustomed to using, roles that they had generally discarded as they acquired expertise. This too may have contributed to their anger.

Another of our studies illustrates the nature of domain-specific, classroom-bound pedagogical knowledge, which is built up over time and may not be applicable to other domains in which individuals interact (Carter and others, 1987). It also reveals a humanistic side to experts that is yet to be demonstrated as clearly among novices and advanced beginners. Experts, advanced beginners, and raw novice teachers participated in a simulation in which information about a class was given to them. They received the tests that students had taken, homework assignments that students had turned in, and a set of student information cards containing typical academic information and some personal notes about the students, their families, and their social
behavior. The simulation required the subjects to imagine taking over such a class in the fifth week of school, after the regular teacher had to leave because of an emergency. The novices in this study worked very hard trying to sort student information cards into piles. Here are some quotations from the protocols obtained in the study.

I sorted the bad kids from the good kids from some of the ones that were just good natured, if they liked to work, that type of thing. And I would do that if I started writing my own comments. If I had the class for a while, I would tend to still categorize them.

I went through her student cards and also went through the test scores and tried to divide the students into three groups, one group which I thought might be disruptive, one group which I thought would not be disruptive and that wouldn’t need intense watching. The third group I really didn’t know because the back of the card was blank. So it was classified later. I realized not all the disruptive students were getting bad grades. I decided to sort of rank cards from what I thought would be the best student from the top to the obviously poorer students going down the stack just to get some sort of an idea of ranking.

This behavior was in marked contrast to that of the experts. Experts were considerably less interested in remembering specific information about students than were the novices. Moreover, experts did not trust information left to them by a previous teacher. They believed that the information was useless because they knew that children make their own deals in every classroom. Information that the child was unmotivated or highly intelligent or disruptive was not thought to be as generalizable as, say, information on a medical record reporting the child to be hypertensive or hypoglycemic. The teachers had learned that every child takes on a different character in every classroom and that educational records, unlike medical records, cannot be trusted. Because of this and because of their generic view of students—seeing them all basically as alike and teachable (Calderhead, 1983)—the experts in our study had no reason to spend time on the particulars reported in the student information cards. The experts spent their time looking at the tests and the homework assignments that students had turned in, trying to understand, at some deep level, something about what students knew. When questioned about why they did not use the student information cards, the experts responded as follows:

I just don’t think names are important as far as this point in time. I haven’t met the kids; there is no reason for me to make any value judgments about them at this time. And so she [the previous teacher] had a whole little packet of confidential material that I looked at, and it had trivial little things about where the parents worked and this kid was cute or something like that, and that to me is not relevant.

Especially when I start fresh, I start from a clean slate. I usually always try to . . . I like getting a little background on the students in that there are going to be severe problems or someone may need special attention on certain things, you know, learning areas, but, in general, it’s a conglomeration of the students. I like to learn from them and develop my own opinions.

It was a typical classroom, some problem kids that need to be dealt with. And you have to take that into consideration when you’re developing some kind of plan for them. There are the bright kids that were highly self-motivated. There were your shy kids. It was a typical class.

I didn’t read the cards. I never do unless there’s a comment about a physical impairment such as hearing or sight or something I get from the nurse. I never want to place a judgment on the student before they start. I find I have a higher success rate if I don’t.
Among the reasons given by the experts for their distrust of the information left for them about each student was their belief that students act differently in different environments—a belief in accord with that of most personality theorists. Their unwillingness to examine the records seems to be a conscious act by these teachers to prevent expectations from forming too early and to ensure that the beliefs they form about students are derived from their own personal experience. This is behavior that is quite considerate of students; it is responsible professional behavior. The experts may ignore student information also because they possess a sense of self-efficacy and have positive expectations. With some uniformity, the experts seem to believe that every child can learn and that they personally can teach every child assigned to them. They seem to attribute the level of student performance not to ability but to effort or family—external and alterable loci. For their own behavior, the locus of control appears to be internal. They take personal responsibility for their success and failure, an example of which was seen in the anger expressed by the expert teachers but not the novice or advanced beginners in the teaching situation described above.

That expert pedagogues use less information than novices or advanced beginners was also found when experienced and novice physicians reviewed applicants for internships and residencies and when experienced and novice financial advisers reviewed financial statements of companies (Johnson, 1988). Experience in a particular domain teaches one what is worth attending to and what is not.

It is hard to speculate on what someone would do in a new situation, but this kind of specialized knowledge probably does not transfer well across domains. It is very likely that when expert teachers join a social club, attend a professional conference, or register to take courses at graduate school, they act like novices. That is, they try to categorize people, grouping them into piles, as novice teachers do with their first class of students. We have increasing understanding that knowledge is, for the most part, contextually bound. As Brown, Collins, and Duguid (1989) put it, cognitions are situated; they are not adrift in the brain, unconnected to actions and situations. The road to transfer across situations appears to be a rocky one. Transfer does not usually appear spontaneously. It usually does not occur without cognitive work, some form of mental effort (Perkins and Salomon, 1989). Thus, we can anticipate that expert pedagogues, like other experts, will excel mainly in their own domain and in particular contexts within that domain. Their expert knowledge will not transfer automatically across domains.

**Proposition two: experts often develop automaticity for the repetitive operations that are needed to accomplish their goals**

Glaser (1987) notes the efficient decoding skill of the expert comprehender in reading as an example of the way automaticity frees working memory to allow other, more complex characteristics of the situation to be dealt with. Examples of the automaticity or routinization of some teaching functions among expert teachers are abundant. For example, Leinhardt and Greeno (1986), studying elementary school mathematics lessons, compared an expert’s opening homework review with that of a novice. The expert teacher was quite brief, taking about one-third less time than the novice. This expert was able to pick up information about attendance and about who did or did not do the homework and was also able to identify who was going to need help later in the lesson. She elicited mostly correct answers throughout the activity and also managed to get all the homework corrected. Moreover, she did so at a brisk pace and never lost any control of the lesson. She had routines for recording attendance, for handling choral responding during the homework checks, and for hand raising to get attention. This expert also used clear signals to start and finish the lesson segments.

In contrast, when the novice was enacting an opening homework review as part of a mathematics lesson, she was not able to get a fix on who did and did not do the homework, she had problems with taking attendance, and she asked ambiguous questions that led her to misunder-
stand the difficulty of the homework. At one time, she lost control of the pace. She never learned which students were going to have more difficulty later on in the lesson. Of importance is that the novice showed lack of familiarity with well-practiced routines. She seemed not to have habitual ways to act. Students, therefore, were unsure of their roles in the class.

In a small study by Krabbe and Tullgren (1989), the routines of novice and well-regarded experienced teachers, whom I will call expert teachers, were assessed. English and language arts lessons at the junior high school level were analyzed. The experts took an average of fourteen minutes to introduce a literature lesson, while the novices took two minutes to do so. The experts needed that much time to follow a routine for the set inducement or introductory phase of the daily lesson. First, they briefly stated the immediate objective of the activity (for example, “We will discuss several ways that we can learn about the qualities of people”). Then they gave clear and explicit directions about what they wanted students to do (for example, “Put everything away; here are three situations for you to think about answering”). Then they created a positive environment for the phase of the lesson that would follow. The experts found ways to increase student involvement, often arousing curiosity through use of analogies that had something to do with the central concept and theme of the lesson. The goal of the lesson was apparent throughout their introduction. This three-step routine was also accompanied by a mood shift among the expert teachers from humorous and playful at the beginning of the introduction to serious and businesslike as the presentation, discussion, or oral reading phase of the lesson drew closer (Krabbe et al., 1988). This regularly occurring pattern of teaching, this routine, was not evident when the videotapes of the novice teachers were analyzed. Krabbe and Tullgren (1989) also identified a routine in the way that the presentation phase of the lesson was run by the experts. The expert teachers introduced material gradually and in hierarchical order, illustrated their points by using student background and daily experiences, and provided practice opportunities as they went along. Novice teachers during this phase of the lesson tended to ask text-specific factual questions until the lesson was over. No sense of a routine was noted in the way the novices taught a literature or language arts lesson.

The well-practiced routines of expert surgeons, ice skaters, tennis players, and concert pianists (Bloom, 1986), no less than expert teachers, are what give the appearance of fluidity and effortlessness to their performance. What looks to be so easy for the expert and so clumsy for the novice is the result of thousands of hours of reflected-on experience. But once again we may speculate that the expert teachers have more than just efficiency, effectiveness, and student achievement in mind as they develop their routines. Such routinization frees the mind so that people may attend to many aspects of the situation in which they find themselves. The mind is a very limited information processor. A concert pianist with no routines would be mechanical, paying little attention to the audience, the conductor, the acoustics, the subtle and unique elements that are present in each performance. Thus routines are so well honed that the pianist’s mind is free to process much more than the position of her fingers on the keyboard. Similarly, if all the attention of a teacher were directed at simply keeping the instructional elements of a classroom moving along the proper course, the highest levels of thinking would rarely be in evidence, and the affective and moral dimensions of classrooms would be unnoticed.

Support for this thesis may be found in the classrooms of novice teachers such as the one studied by Leinhardt and Greeno (1986). With no routinization of the opening homework review, the novice could not find out which of the students had had a troubled night at home the evening before, though the expert teacher could. Routines among the experts studied by Krabbe and Tullgren (1989) may have allowed them to allocate attention to matching the content to be learned to the students’ personal knowledge and common experience. That is, the quality of a teacher’s pedagogical content knowledge (the teacher’s explanations, metaphors, analogies, and other transformations of what is to be taught into something more easily learned) may depend in part on supportive routines. This is because pedagogical content knowledge is often
developed on the run, during interactive instruction, when attention to simultaneous events is required. Thus, routinization may promote interpersonal and personal relations in classrooms as well as it promotes instructional goals.

Proposition three: experts are more sensitive than novices to task demands and the social situation when solving problems

Glaser (1987) notes that the mental models that experts develop to guide their behavior are constrained by the requirements of the situation in which they must work. Housner and Griffey (1985), in a study of experienced and novice physical education teachers, provide evidence of the sensitivity of experienced teachers to those issues. They found that the number of requests for information made by experienced and novice teachers during the time they were planning instruction was about the same. Each group made reasonable requests for information about the number of students they would be teaching, their gender, their age, and so forth. But in two areas, the experienced teachers made many more requests than did the novice teachers. They needed to know about the ability, experience and background of the students they were to teach, and they needed to know about the facility in which they would be teaching. In fact, five of the eight experienced teachers in this study of planning and instruction demanded to see the facility in which they would teach before they could develop their plan. Novices made no such requests. The experienced teachers were sensitive to the social and physical environment under which instruction was to take place.

When actually performing in the teaching role, the experienced teachers implemented changes in their instruction more often than did novices, using social cues to guide their interactive instructional decision making. The experienced teachers used their judgment about student performance as a cue to change instruction 24 percent more often than did novices, their judgments about student involvement 41 percent more often, student enjoyment of the activities 79 percent more often, and their interpretation of mood and student feelings 82 percent more often. The novices used student verbal statements about the activity as their primary cue for instituting a change in their instructional activity, responding to these cues 131 percent more often than did the experienced teachers. Clearly, the novice teachers changed what they were doing primarily when asked to; they seemed unable to decode the social cues emitted by students about the ways in which instruction was proceeding. The experienced teachers, however, were far more sensitive to the social cues emitted in the situation and used these social cues for adjusting their instruction. Once again, we have evidence that experts behave in ways that we would judge more considerate of their students than the ways in which novices behave. Their experience has taught them how to read the more subtle cues emitted by their students, and this makes them more sensitive to the students’ needs. Their reputations for effectiveness are likely to be due in part to their heightened social sensitivity.

Proposition four: experts are opportunistic in their problem solving

Glaser (1987) reports that experts are opportunistic in their planning and their actions. They take advantage of new information, quickly bringing new interpretations and representations of the problem to light. Novices are less flexible. Borko and Livingston (1988) discuss these same behaviors among novice and expert teachers. The term that these researchers use to characterize the expert teacher whose lessons have an opportunistic quality is the improvisational performer. They see the expert teacher as having a well-thought-out general script to follow but being very flexible in following it in order to be responsive to what students do. One expert, discussing his planning, made clear the improvisational aspect of teaching: “A lot of times I just
put the objective in my book, and I play off the kids." This expert also described his interactive teaching as similar to a tennis match: "I sort of do a little and then they do a little. And then I do a little and they do a little. But my reaction is just that, it's a reaction. And it depends upon their action what my reaction's going to be."

Borko and Livingston (1988, p. 20) report that 'the success of the expert teachers' improvisation seemed to depend upon their ability to quickly generate or provide examples and to draw connections between students' comments or questions and the lesson's objectives." This was not the case when the novices were teaching. All three of the novices in this study ran into problems when students made comments or asked questions requiring explanations that had not been planned for in advance. Novice teachers were sometimes unable to maintain the direction of the lesson when they had to respond to student comments or questions. This was true even when the issues brought up by the students were relevant to the topic of the lesson. Experiences such as this led two of the novices to prevent students from asking questions and making comments while they presented their lesson. Although he valued student responsiveness, Jim, one of the novices, reasoned this way (p. 26): "I think . . . because I'm not that proficient yet in handling questions, it's better to cut off the questions, just go through the material, because it'll be much clearer to them if they just let me go through it . . . I don't want to discourage questions, but there are times I'd rather get through my presentation and then get to the questions."

Opportunistic teaching is apparently much more difficult for the novice than for the expert. For novices, the pedagogical schemata necessary for improvisation or opportunism seem to be less elaborate, less interconnected, and clearly less accessible than are those of the experts. It is the flexibility arising out of self-confidence that allows the expert teacher to capitalize on the instructional opportunities that present themselves. They can personalize instruction, developing pedagogical content knowledge on the run, and this allows them to fit the lesson to the students' behavior in ways that the novice cannot. This ability must make an expert appear more sensitive and responsive to student needs than would a novice. The experience and confidence of the experts allow them to appear more considerate of students—more caring, flexible, interested in what their students know, and so forth. The display of such humanistic and effective interpersonal qualities is still beyond the reach of the typical novice.

**Proposition five: experts' representations of problems and situations are qualitatively different from the representations of novices**

Chi et al. (1988) note that experts seem to understand problems at a deeper level than do novices. Experts apply concepts and principles that are more relevant to the problem to be solved. Novices' understanding seems to be at a more superficial level; they show less evidence of principled reasoning. We find some support for this general statement in studies of expertise in the pedagogical domain. In one small study of ours, Hanninen (1983) created realistic scenarios about educational problems associated with gifted children. One scenario, for example, described Mark, an eight-year-old Asian boy with severe hearing deficits who likes mathematics and science and has a strong interest in computers. Scenarios describing educational problems of this type were presented to fifteen subjects. Five of the subjects were expert, experienced teachers of gifted children; another five were equally experienced teachers but without any background in gifted education; and five more were novice teachers of the gifted, still working on their certification.

The opening sentences of some of the protocols revealed much about the thinking of experts and novices. The opening sentence from one novice reads, "Mark seems like a very talented individual with many diverse interests." Another novice comments, "Mark should be encouraged
by his teacher to continue his science experiments and work on the computer.” From an experienced teacher who was a novice in the area of gifted education, we have “He should be able to pursue his interests in greater depth.” In contrast to these banal, unsophisticated beginnings to essays that attempted to address Mark’s needs, in which superficial characteristics of the problem were noted, one expert began right off with “Mark’s needs can be broken into three broad areas: academic enrichment, emotional adjustment, and training to cope with his handicap.” This essay was a more organized and sophisticated representation of the problem than was obtained from the novices. The experts also concentrated more on the affective characteristics of Mark’s life than did the other teachers. This is a common pattern among experts and will be discussed in more detail below.

If one views pedagogical knowledge as a complex multidimensional domain of knowledge requiring sophisticated thinking, then it could be argued that the classification of a problem as solvable by using Newton’s second law—that is, considering it a conservation-of-energy problem—is no different from classifying Mark’s educational needs as falling into three categories and describing action relevant to each of those categories. This was an appropriate representation for a problem in the pedagogical domain.

The scenario methodology that we used to learn about teachers’ thinking was used in a better-designed study by Nelson (1988), in which expert and novice physical education teachers were the subjects. She concluded that experts “displayed a greater variety of application of sound principles of teaching” (p. 25) than did novices. The experts were also more creative and thorough in describing ways to address teaching problems and provided more solutions to each problem that they addressed. In a different study, Peterson and Comeaux (1987) used videotapes to elicit comments from experienced and novice teachers. They found that the comments of experienced teachers “reflected an underlying knowledge structure in which they relied heavily on procedural knowledge of classroom events as well as on higher-order principles of effective classroom teaching” (p. 327).

Similarities in the two studies are quite apparent. An expert in Nelson’s (1988) study says of a problem with an exercise program designed for an overweight child, “I’d find something positive about his workout . . . If I don’t give him some positive reinforcement, I may lose his dedication to the task” (p. 25). And an experienced teacher in Peterson and Comeaux’s (1987) study says about a teacher returning an essay test, “I guess before he handed them back, it might have been a good idea if there was an excellent paper there to have read it with no name, or excerpts from it, or at least on the board outline what a good answer would have been—that type of thing. He might have made some comments of errors that were made, again with no names, that were misconceptions, and clear those up with students right away. You can use the test as a learning experience rather than just hand it back, to put away, or throw away probably” (p. 328).

In the comments of both the expert and experienced teachers, we see evidence of principled thought, the former enunciating a principle about reinforcement and motivation, the latter enunciating a pedagogical principle about the usefulness of tests as learning experiences separate from their function in evaluation. Such reasoning was not typical of the responses of novices. Moreover, the comments about motivation and the use of tests for learning experiences (not just for feedback, reward, or punishment) show interest in considerate teaching. The word genuine characterizes a good deal of the teaching that experienced teachers do. It is teaching primarily for growth and improvement rather than for sorting children out along an ability continuum.

In another study of ours (Stein et al., forthcoming), we looked at the ways that expert teachers predict how students will respond to mathematics and science items used in the National Assessment of Educational Progress. From the protocols obtained while the subjects thought aloud, we learned that experts named or labeled items in a much more detailed and specific way than did novices or advanced beginners. The experts also engaged in a task analysis of the problem in a way that was quite sophisticated. They analyzed the demands of the task repre-
presented in the item to determine what sorts of problems students might experience with them. Task analysis was coded in their think-alouds when the subjects verbalized something about the reasons for an item’s difficulty or when they traced out the various steps or competencies that a student would need to answer an item correctly. Eighty percent of the experts analyzed the task demands of the items; they did this for between one and four of the five items for which they had to think aloud. Among the novices and the advanced beginners, only 50 percent of each group engaged in task analysis of the items, and when they did so, it was for only one of the five items that they analyzed. The task analyses of the experts were also more elaborate or more clearly formed than those of others.

The experts also differed in their inferences about the student cognitions used in answering an item. Experts seemed to have a fund of knowledge about the way students thought and how that thinking interacted with the content of the specific mathematics or science items. In addition, the experts seemed able to think through the misalgorithms that students might apply. The experts had more experience dealing with student errors and therefore knew what types of errors students might make. Novices rarely discussed the issue of misalgorithms that students might apply to solve a problem. We concluded from this study that experts in mathematics and science teaching were more likely than novices and advanced beginners to represent the test items the students would address in a more sophisticated way because of their better labeling of problem types and that they gained insight into the nature of a particular problem type by more frequently doing a task analysis of it from the students’ perspective. From the labeling and task analysis, the experts could more often predict the kinds of errors that students would make when attempting to answer test items. Since their predictions were more accurate, they appeared to be better explainers than novices or advanced beginners and more understanding of their students’ ways of thinking.

**Proposition six: experts have fast and accurate pattern-recognition capabilities; novices cannot always make sense of what they experience**

Accurate interpretation of cues and recognition of patterns reduce a person’s cognitive processing load and allow the person to instantaneously make sense of a field. For example, quick pattern recognition allows an expert chess player to spot areas of the board where difficulties might occur. Novices are not as good at recognizing such patterns, and when they do note them, they are less likely to make proper inferences about the situation.

In one of our studies, we showed subjects slides of classroom scenes and asked them to interpret what they saw. Each slide was viewed briefly three different times. After the second viewing of a slide, one expert in science said, “It’s not necessarily a lab class. There just seemed to be more writing activity. There were people filling out forms. It could have been the end of a lab class after they started putting the equipment away.” After the third viewing of the slide, the expert said, “Yeah—there was . . . very little equipment out and it almost appeared to be towards the end of the hour. The books appeared to be closed. Almost looked like it was a cleanup type of situation.” Novices did not usually perceive the same cues in the classroom and therefore could not make the inferences that guided the expert’s understanding of the classroom. The expert, by the way, was absolutely correct. It was a cleanup kind of activity.

In another study, novice, advanced beginner, and expert teachers simultaneously viewed three television screens, each depicting a different group working in the same class. We saw the same phenomena at work here as in the task using slides (Sabers et al., 1991). During a think-aloud viewing of the videotape, one expert commented, “Left monitor again . . . I haven’t heard a bell, but the students are already at their desks and seem to be doing purposeful activity, and this is about the time that I decided they must be an accelerated group because they came into the
room and started something rather than just sitting down or socializing.” In fact, the students in
the scene shown on the left monitor did begin working as soon as they entered the classroom
and continued working throughout the entire instructional period. To us, as well as to the experts,
this group of students seemed to exhibit a lot of internal motivation. Further, just as this expert
noted, this was an accelerated group: it was a science classroom for students identified as gifted
and talented.

We regard the reading of a classroom, like the reading of a chess board, to be, in part, a matter
of pattern recognition based on hundreds of thousands of hours of experience. The ability
of novices or other relatively inexperienced teachers to reliably interpret classroom information
is limited precisely because of their lack of experience. The information related to pedagogical
events may be so rich and complex that novices and advanced beginners simply cannot agree on
what is seen. In the study where they monitored three television screens simultaneously, novices
and advanced beginners seemed to experience difficulty in making sense of their classroom
observations and in providing plausible explanations of what was occurring within the classroom.
For example, we obtained these two comments from advanced beginners who were asked to
describe the learning environment in the classroom that they were observing:

> It looked . . . I wouldn’t call it terribly motivating. It was, well, not bored, but not enthusiastic.

> Very positive as well as relaxed. Very positive . . . it’s good to be able to focus [student] energy into a group situation, yet at the same time, accomplishing the work that they need to do for the class and also lending to the relaxed feeling of the classroom.

Such contradictions were common. Even more discrepancy was noted when these subjects
were asked to describe the students’ attitudes toward this class. For example,

> It didn’t look like it was a favorite class for most of them. One boy looked kind of like, “Oh no, it’s not this class again.” They didn’t look overwhelmingly enthusiastic to be there.

> They seemed pretty excited about the class, excited to learn and a lot of times it’s hard to get students excited about science, but this teacher seems to have them so that they are excited about it. They’re willing to work and they want to learn.

As a group, these advanced beginners, in their first year of teaching, seemed unable to make
sense of what they saw. They experienced difficulty monitoring all three video screens at once.
Thus, they often reported contradictory observations and appeared confused about what they
were observing and the meaning of their observations. Because novices are much less familiar
with classroom events than advanced beginners, they often appeared even more overwhelmed.
Many of them expressed difficulty in monitoring all three video screens at once; generally, they
appeared able to focus on and make sense of only one screen. Since this limited their observa-
tions, they also made errors and contradictions when they were asked about specific events.
They were unable to see the overall patterns in the information presented to them.

Another of our studies also showed this difference in interpretive competency between experts
and novices (Carter and others, 1988). In that study, subjects viewed a series of slides depicting
science or mathematics instruction over a class period in a high school. The subjects held a
remote control and were told to go through the fifty or so slides at their own pace, stopping to
comment on any slides that they found interesting. Novices and advanced beginners seemed to
show no particular pattern in what they stopped to comment on and showed the same kinds of
contradictions in their interpretations that we found in the study using videotapes. That is, one
novice might say “Everything looks fine, they’re all paying attention,” and another novice might
say, “It looks like they’re starting to go off task, they’re starting to drift.” A pattern was noted
among the experts that was quite different. The experts, more often than the subjects in the other
groups, found the same slides worth commenting about and had the same kinds of comments to
make. For example, three experts made these comments on slide 5:

It's a good shot of both people being involved and something happening.
Everybody seems to be interested in what they're doing at their lab stations.
Everybody working. A positive environment.

And two experts offered these comments on slide 51:

More students with their books closed, their purses on their desks, hands folded, ready
to go.
Must be the end of class and everybody is getting ready for the bell to ring.

This reduction in variance by the experts is particularly noteworthy. It means that they have
learned to pay attention to some of the same things and to interpret visual stimuli in the same
way. This similarity in what is attended to and how it is interpreted is what we hope for when
we visit an expert ophthalmologist or automobile mechanic. Novices, advanced beginners—
anyone in the early stages of skill acquisition—simply will not have acquired enough experi-
ence for that.

The ability to quickly make sense out of what is seen was demonstrated in a unique way by one
of the experts in the study using slides. In the classroom that had been photographed, a girl had
entered in a gray jacket, gone to her desk, put her purse down on the floor, and looked straight
ahead throughout the lesson, neither opening a book nor engaging in any aspect of instruction or
student conversation. She appeared clothed in a heavy mantle of grief. Near the end of the
lesson, she silently started to cry. Tears streamed slowly down her cheeks, unnoticed by her
teacher or her peers. As the bell rang, she bolted and ran from the class. From static slides, shot
with a wide-angle lens, the girl’s behavior could hardly be noticed. Yet one expert, as he got to a
slide near the end of the tray, said, "There's something wrong with the girl in gray.” And then, as
he looked at the next slide, he said, "Yep, there's something really making her unhappy and it has
nothing to do with this class.” We think this is a remarkable example of accurate processing
of subtle patterns in the visual field. We commented about this skill in social sensitivity when we
discussed proposition three, above. And we will comment on a related phenomenon as we
discuss proposition seven, next.

Proposition seven: experts perceive meaningful patterns in the
domain in which they are experienced

Chi et al., (1988) point out that the superior perceptual skills of experts are due not to any innate
superior perceptual abilities but to the way that experience affects perception. After one hundred
thousand x-rays or ten thousand hours observing students, what is attended to and how that
information is interpreted are very likely to have changed. In another experiment with slides
of classroom scenes (Carter and others, 1988), we flashed slides on the screen for only a very
brief time and asked experts, novices, and advanced beginners to tell us what they saw. The
responses of the novices and advanced beginners to the slides were clearly descriptive and
usually quite accurate.

Novice: A blond haired-boy at the table, looking at papers. Girl to his left reaching in front of
him for something.
Advanced beginner: [It’s] a classroom. Student with back to camera working at a table.

Advanced beginner: A room full of students sitting at tables.

In contrast to these literal descriptions, typical of novices and advanced beginners, some of our expert teachers often responded with inferences about what they saw:

It’s a hands-on activity of some type. Group work with a male and female of maybe late junior high school age.

It’s a group of students maybe doing small-group discussion on a project as the seats are not in rows.

For experts, the information that was often deemed important was information that had instructional significance, such as the age of the students or the teaching-learning activity in which they were engaged. They perceived more meaningful patterns than did novices. Nelson (1988) replicated these findings of ours, using expert and novice physical education teachers. When viewing a slide intended to show a common management problem, a student not dressing for the gym period, a novice teacher somehow misinterpreted the scene: “What I’m assuming is that this is an on-looker. Somebody [who’s] just walked in. Maybe someone that’s late to class or someone who’s hesitant about doing gymnastics, a little scared so they’re off in another area just watching” (p. 15). An expert viewing the same slide perceived more than the girl’s lack of gym clothing. She saw the whole instructional situation in a more global way and made more meaning of it:

Here is one girl I noticed earlier who is not dressed out [sic]. She could have a doctor’s excuse or something, but she’s far away from the remainder of the class and she should be involved, maybe with spotting, or at least in a closer proximity to the rest of the students. She needs to learn just like everyone else in the class. The teacher [then wouldn’t] need to be worried about what she is doing, either. If something is missing from the teacher’s desk or any of the students’ belongings, [that girl] may have to take the responsibility. [Also], the doors are so close by, if she wants to leave there’s always a possibility, and the teacher is responsible for her. She’s just not involved in the class in any way.

(pp. 15–16)

In any field, the information that experts extract from the phenomena with which they are confronted stems, in part, from the concepts and principles that they use to impose meaning on phenomena in their domain of expertise. That is, experts in all domains appear to be top-down processors. They impose meaning on the stimuli in their domain of expertise. In education, one such concept used to interpret phenomena is attention, or involvement. The physical education expert quoted above is interpreting the slide with this concept in mind. In our study of the interpretation of slides, a focus of the experts was on the notion of work: “students working at the blackboard,” “students working independently,” “teacher looking over a person working in lab,” and so on.

This work orientation, of course, is part of what promotes high rates of achievement among the students of experts. But some characteristics of the experts that are less clearly tied to effectiveness (though contributing to it) have also been found. These have more to do with the responsibility side of teaching. For example, we have found evidence from two studies of ours (Clarridge, 1988; Rottenberg and Berliner, forthcoming) that expert teachers take student responsibility in a lesson into account, expecting students to be in some way involved in the creation of their own knowledge, perhaps through discussion, perhaps through cooperative learning, perhaps through
questions or projects. Somehow, the experts seem to communicate this sense of responsibility and are sensitive to it when discussing their views of classes. Evidence for this was found in Claridge’s (1988) study in which videotapes were rated by a specialist in non-verbal communication. The specialist found the expert teachers to be high in incorporative behavior, behavior that invites the students to work jointly with them. The specialist also found that novice and advanced beginners set up barriers to keep authority in their own hands. (The tapes, of course, were rated without knowledge of the experience level of the teachers that were viewed.) Furthermore, expert teachers seem to be unusually sensitive to the affective concerns of the students they teach (Nelson, 1988; Rottenberg and Berliner, forthcoming). The expert who recognized the unhappiness of the student from a minimum of cues in the study discussed above was displaying this kind of social sensitivity. This was also true of the physical education teachers described earlier.

A physicist may bring to bear Newtonian laws to make meaning of a problem in physics. A biologist may bring to bear concepts of homeostasis or ecological niche to make meaning of a problem in biology. A chemist, auto mechanic, and an engineer will also bring to bear on the problems that they face the most salient and useful concepts that they possess. Among the salient and useful pedagogical concepts with which teachers make meaning from the phenomena that they encounter in their work are attention, work, responsibility, and affect. While the first two of these concepts deal with effectiveness more than responsibility in teaching, the latter two concepts deal explicitly with issues of responsibility more than effectiveness. Perhaps of greater interest is that among experts, it appears that effectiveness and responsibility are fused concepts.

Conclusion
The results of the studies described in this selective review appear to be clear. First, expert teachers share characteristics with experts in other domains. Second, the domain-specific knowledge of experts is of a rather sophisticated nature. The collection of evidence supporting these two points is important for the profession. Finally, the evidence about experts suggests that their unique reputation is not based merely on their effectiveness as instructors. Certainly, the evidence supports the claim that they think and act differently from novices in ways that are likely to promote their effectiveness as instructors. But a review of the same data suggests that the experts also think and act differently in ways that promote responsible instruction. And these differences in thinking and acting do not appear to be attributable to differences in age and life experience, though such differences certainly exist; rather, they appear to result from reflected-upon classroom experience, which leads the experts, for the most part, to teach in ways consistent with the complementary synthesis model described in Chapter One of this book. The experts seem to understand better than other teachers that the two approaches are mutually interdependent. They appear to believe that effectiveness can be achieved through responsible teaching and that being responsible entails being effective. That is, a responsible teacher owes students the opportunity to obtain the knowledge and skill needed to succeed in life, and an effective teacher owes students civility and consideration. With rare exceptions, the experts that have been studied demonstrated this sense of obligation toward their students. They also had a positive motivational system at work in their classrooms, a recognition of individual differences among their students, a belief in their own efficacy and their students’ ability to learn, and a concern with both the affective and the effective elements of the classroom environment in which they worked.

The research on expertise has proved to be useful in policy analysis. Understanding the contextualization of expertise helps us to understand the limits of what we can expect from teachers and the irrationality of the expectations that we sometimes have. Learning that it takes considerable time to acquire competence in the pedagogical domain, let alone expertise,
changes the way we think about support systems for the beginning teacher and the limits of teacher education programs. Learning what experts attend to, what they find worth remembering, how they implement routines, and how they maintain a classroom that is considerate of their students can help in designing programs of teacher education that are more focused on the acquisition of the pedagogical knowledge needed to teach both responsibly and effectively. The research has also provided us with ways to think about the growth or development of different kinds of knowledge in the pedagogical domain. Theories about the development of pedagogical expertise have been proposed that fit the existing data quite well. An example is my own description of a five-stage theory of the development of expertise, which posits the stages of novice, advanced beginner, competent performer, proficient performer, and expert (Berliner, 1989; based on work by Dreyfus and Dreyfus, 1986). Developmental theories of knowledge growth have implications for the kinds of assessments, the content of assessments, and the timing of assessments that will be used in the evaluation of teachers.

Expertise in pedagogy is now seen as a synthesis of what we call responsible and effective instruction. It appears to be a complex and highly sophisticated kind of domain-specific knowledge and skill, developed slowly over many years by highly motivated individuals. It is not a level of development that is obtained by everyone. The small number of teachers who achieve this status should be honored. They are the people whom we should ask the public to watch when the public is criticizing education. Few among the critics could ever match the experts' pedagogical skills day after exhausting day, year after exhausting year.

Part 6
Commentaries
As the chapters and artifacts in this section illustrate, teacher learning is the core of the teacher education agenda both for prospective teachers and experienced teachers. In the 1980s and 1990s, teacher learning was also the explicit focus of the reform agenda. Federal funds through the Goals 2000: Educate America Act, passed in 1994, provided funds for teachers and administrators to learn how to improve student achievement. Title II of the Amendments to the Higher Education Act in 1988 provided three separate categories of grants to improve teaching quality, targeting prospective teachers’ learning as well as that of experienced teachers. Foundations have also supported reform. For example, in 2002 the Carnegie Corporation of New York’s Teachers for a New Era project (in partnership with the Ford Foundation and the Annenberg Foundation) began funding universities to work with local school districts to reform preservice teacher education and the support for continued teacher learning following graduation. There are now eleven universities involved, all striving to improve teacher learning and, therefore, student learning (www.teachersforanewera.org).

The issues surrounding teacher learning are the subjects of many arguments as critics of preservice teacher education continuously challenge the curriculum in schools, colleges, and departments of education. For example, in a recent column in Newsweek, George Will (2006) attacked teacher education curricula that deal with topics such as social justice and awareness of how identities are performed in school as “enemies of rigor.” In the Journal of Teacher Education, Sandra Stotsky (2006) called for accountability of preservice teacher education to be moved to the departments housing the disciplines, which would offer a Master of Arts in Teaching (MAT) degree.

If entry into teaching Grades 5 to 12 required the completion of an M.A.T program consisting of, say, four authentic graduate courses in the discipline and no more than one methods course followed by an apprenticeship in the schools that included seminars on what was taking place in the classroom, neither teacher tests nor departmental exit exams at the undergraduate level would be necessary.

(p. 263)

Although the academic home for teacher education, the nature of the curriculum, and the balance of subject matter and pedagogy have long been topics for debate, the research base—empirical evidence to support the location and nature of instruction, the curriculum, the qualifications of instructors, etc.—is very thin (Cochran-Smith & Zeichner, 2005). Indeed, even with the publication of the two previous handbooks on research on teacher education and with the proliferation of international journals devoted to teacher education in the past ten years (e.g. Studying Teacher Education; Asia-Pacific Journal of Teacher Education and Development) there is little data to provide links between an
individual's knowledge, their learning within a teacher education program, their actual teaching in schools, and their students' learning. Using the chapters and artifacts in this section as a springboard, I will discuss five areas that we, as researchers, must consider in order to impact our ability to conduct rigorous research on teacher learning that can inform policy and practice.

DESIGNING AND CONDUCTING LONGITUDINAL STUDIES OF LEARNING TO TEACH

There is considerable agreement that the field of teacher education in general and the study of teacher learning in particular would benefit greatly from more longitudinal studies of teacher learning over time and how that learning plays out in practice (Wilson et al., 2001; Clift & Brady, 2005). Since publication of the Clift & Brady review, a few more studies have been published. These studies rely mainly on qualitative designs and are based on interviews with several novice teachers or employ case study designs that include classroom observations. Several studies attempt to represent multiple perspectives on the learning and teaching of novice teachers, as the co-author is often the former student (now teacher) working with the researcher to make sense of the way in which learning opportunities within the preservice program were continued in practice. The texts include the voice of both the researcher and the novice teacher, thus providing two views of the transition from student to full-time teacher. These case studies identified building level factors (e.g. Smagorinsky et al., 2004; Bickmore et al., 2005), district level factors (e.g. Grossman & Thompson, 2004), and personal factors (e.g. Smulyan, 2004) that influence teachers' learning and their teaching practice, including the decision by some novice teachers to move to contexts that are more congruent with their beliefs, practices and intentions regarding teaching and continued learning.

In one longitudinal, intensive study in the Boston area, Susan Moore Johnson and colleagues (2004) carefully documented school contexts that were able to recruit and retain talented novice teachers over five years. They studied the building level factors that encouraged fifty teachers to continue learning about how to best teach and reach their students most effectively, particularly in schools with well designed induction and mentoring programs.

Notably each of these schools places a high value on adult learning and professional growth. There was an underlying assumption that students would benefit as teachers became more knowledgeable and skilled. Teachers' development was a purposeful, community endeavor, not the lone effort of a motivated, entrepreneurial individual. (p. 237)

As we think about the importance of longitudinal work, it is important to note that all of the lead researchers cited above are tenured professors at their respective institutions. They can invest several years in data collection and analysis because they are not under pressure of tenure review. It is also important to note that much of this research, including mine, has been externally funded, mostly through the federal grants.

To increase the number of longitudinal studies, funding is required, but additional factors impact longitudinal designs, particularly those involving more in-depth case studies. My own research team (Clift et al., 2006) documented the challenges that we faced as we followed thirteen students through their teacher education program and into their first years of teaching (or not teaching). Ownership of the study, shifting roles and
responsibilities, and the intersection of personal and professional goals affected the composition of the research team over time. As team members left the project because their professional goals did not include participating on one project over five or more years, knowledge was lost. Not only their knowledge of the project and all of the participants, but the knowledge they brought to the team because their areas of interest informed our discussions and interpretations of the data. As new members came on to the project, time was lost as they struggled to learn about methodology, the participants, and the team culture.

As we think about designing longitudinal studies, seeking funding, and forming a research team, we need to think carefully about ways to sustain participation over time by research team members, as well as by the participants who are allowing us to learn about their learning. There are few methods texts to guide us in this work, which means that the field of research on teacher learning must be as attentive to careful documentation and critique of methods as it is to asking the right questions.

**LANGUAGE, POWER, AND VULNERABILITY**

All of the chapters in this section, in agreement with the essay by Dewey, embrace the view that teachers are continuous students of teaching. Two of the chapters explicitly identify language as an important aspect of that study. Rodgers and Scott focus on the need for preservice teachers and teacher educators to examine how self and identity are formed and reformed as one develops as a teacher. They note that the terms others use to describe the self and the terms one uses to describe oneself work together to define identity in particular contexts and in particular relationships. Rosaen and Florio-Ruane unpack metaphors that overtly and covertly construct the nature of teacher education, teacher learning, and student learning. Their discussion details the ways in which social and cultural factors shape our interpretation of individuals, groups, and events. Both chapters make clear, in different ways, why teachers need to be mindful of the language that shapes their beliefs and practice and be engaged in continuous reflection on the helpful and harmful dimensions of language.

The international community that comprises teacher educators and teachers who are engaged in the self-study of teacher education has often raised questions about the social, emotional, and political facets of language in relation to studying one’s own teaching and learning, as well as when studying others’ learning. In writing about self-study by teacher educators, Bullough & Pinnegar (2004) caution

> The expressed form of self-study is always constructed in relation to the audience being addressed and it is tempered by the recognition of the deep moral obligation teachers have to students. It is here where vulnerability presents a genuine danger, but it is recognized as part of learning, which also involves unlearning. When unlearning, the vulnerability felt by the teacher educator must be managed so that in its expression in teaching and in the reporting of the research no harm is done.
>
>(p. 340)

An investigation of self as learner is an individual, personal, reflective, and political enterprise, particularly concerning those areas that one might like to unlearn. It is one thing when it is private, voluntary and under one’s control. Required sharing of one’s study of self with a teacher, a researcher, or even a peer is something else altogether. As we study learning to teach and teacher learning, and as we engage our students and
colleagues in reflections on the role played by language in the construction of society and self, we do so in institutional and political contexts that may be hostile to what we are learning. Furthermore, as the Will essay quoted at the opening of this commentary illustrates, we must be mindful of the ideologies that oppose and scorn what we are attempting to enable. This makes the study of language, how it constructs and constrains world-views and how it is interpreted differently by different people, even more important. But we must also be mindful of the individual vulnerabilities that are created when a student explores his or her own practice or beliefs in the context of a classroom or research project and the individual and collective vulnerabilities that are created as we use language to challenge language use. As one of my research team members noted, “And I think I have become increasingly comfortable telling you how I feel, but I don’t know if . . . there is definitely a very strong edit button,” (Clift et al., 2006, p. 93). In other words, research on learning to teach and teacher learning does not occur in a linguistic, political, ideological, or power vacuum; attending to this reality deliberately, rather than being surprised by it later, is an important aspect of research design.

**INTRUSION AND THE PROTECTION OF HUMANS**

Westheimer’s chapter raises specific questions about the tenuous balance between respect, competing interpretations, and argument as teachers work in learning communities within their own schools.

Much of the research and practice relating teacher community to teacher learning advocates working together, overlooking differences, and creating friendlier, more open work settings for teachers. More work would be useful that studies power imbalances and the resulting sense of impotence that threaten to undo so many of these well-meaning reforms.

(p. 773)

The presence of a researcher, a documenter of agreements and disagreements, can exacerbate these threats. Even with pseudonyms, the audience who works in the school or community is very likely to read beyond the code names and to be able to identify individuals, places and events. The threat to self and professional identity may not come from being known to a national audience, but to the local audience. Thus, instances of an individual’s learning that are negative or of contexts that are ineffective in terms of promoting learning may result in personal embarrassment or even hostility form one’s colleagues.

For most institutional review boards, the question of any potential harm to human research participants is a key component of approval. Indeed, some boards have been known to disallow any research that involves a teacher studying his or her students (Hemming, 2006). In our review of studies of methods courses and field experiences (Clift & Brady, 2005), we found that many researchers who were studying their own students did not attend to the possibility that these students were engaging in behaviors that were advocated by professors, and that their findings were not tempered with cautions that learning or acting in a certain way occurred as a result of course expectations. Investigating one’s own learning and one’s students’ learning necessitates collecting evidence of learning from multiple sources whenever possible. But even when the investigator is not part of the classroom setting, the study of teacher learning is still affected by the presence of the researcher or the knowledge that one is participating in a study.
Likewise, the researcher is changed by his or her participation. This is particularly evident when an investigator is accepted into a school community and invited to study professional learning with that community. Craig (2003), for example, documented the discomfort she felt when administrators approved of and encouraged her to study teachers’ participation in a school reform effort, her attempts to become accepted, and her subsequent reflections on the situation. Accustomed to working in schools and with teachers, she was surprised to learn that while she was welcomed by the administration, she was not welcomed by many of the teachers. Many of them viewed her presence with suspicion and let her know they were hesitant to talk to her about their perceptions of the reforms. Her notions of working in schools and with teachers were fundamentally changed.

Even as I was drawn in from the margins into YMS’s reform vortex, as my work and my identity as a researcher became questioned in the episode by the school-based educators, and during and after the episode by the school-based educators and after the episode by me. Like the practitioners, I also sought ways to manoeuvre [sic] carefully on the landscape and to avoid landmines such as arriving at a gathering to which I was invited, but not fully welcome. The overall effect, as the reform effort shows, is not one of passing discomfort; it comprises full strength upheaval for all those whose professional lives take shape in reform active contexts with deeply etched social, narrative histories.

( pp. 644–645 )

Studies of teacher learning, whether smaller self-studies, studies of reform, or large scale longitudinal studies in which teacher educators work with others who are in different fields have the potential to challenge even as they inform. As we design and work with our students to design studies of teacher learning, we may need to think beyond the requirements of review boards to consider how our work may impact events, our findings, and our sense of who we are as teachers/researchers/learners.

CHANGES, CHANGES, AND MORE CHANGES

When I was an assistant professor, I was invited to participate in a reform of a teacher education program. Since my field of study was curriculum design and teacher education, it seemed like a natural invitation to accept. The processes and outcomes of our work were recorded in a book chapter ( Clift et al., 1992 ), along with the work of others across the country who were also engaged in teacher education curriculum reform. At the end of our chapter, we recount the dismantling of the program because of state mandates to restrict the curriculum hours devoted to professional education. I was disappointed about the lost opportunity. I had naively thought that once we had negotiated with faculty members and had passed through university and state approval processes, we would then be able to study the program, to investigate student outcomes, and to modify the program based on what we were learning about our students’ learning. I have become more pragmatic over time as I talk with others who have sought to study a given program, only to learn that the program is being modified in the midst of their research. There are political, social, and individual factors that impact program stability over time and, therefore, the opportunity to evaluate program impact.

I now work in a nineteen-year-old department that has experienced eight department heads; five deans; six provosts; and one major reform of the early childhood, elementary,
and secondary teacher education programs. Despite the changes in administration, my colleagues and I are committed to helping teachers learn to understand better and teach more effectively the students with whom they work. Many of us have engaged in the systematic study of our students’ learning. I also work in a state that is divided into slightly less than 900 school districts and ranks in the bottom in terms of equality of education funding across districts. Seven out of every ten schools are operating with a deficit (Illinois Poverty Summit, 2005). Teachers leave high poverty schools and urban schools at higher rates than their counterparts (Klosterman et al., 2003). As I write this, there are major state-wide debates concerning funding for education. Embedded within those debates is funding to support some level of mentoring and induction for new teachers and higher accountability for teachers’ and schools’ productivity. Internal change within institutions and external change brought about by policy are constants.

As we think about designing systematic studies of teacher learning and the contexts (university courses, community experiences, school-based experiences, etc.) designed to support that learning, we cannot ignore the continuous pressures for change that come from national, state, and local origins. We can either lament the presence of constant change or recognize that conditions for teaching and for teacher education are seldom stable. How teachers and teacher educators learn to resist effectively when change is harmful to students and communities and how they learn to adapt to change in ways that are helpful to students and communities are two areas of study that are not well documented in the literature on learning to teach. What is well documented is that the field of research on teacher learning, right now, is dominated by qualitative studies, most of which are small scale and many of which are some versions of self-study.

TRAINING FOR THE STUDY OF LEARNING TO TEACH

A growing number of scholars in teacher education are calling for a rethinking of how we prepare our graduate students to become the next generation of researchers. For example, in the final, synthesis chapter of the report of the AERA Panel on Research and Teacher Education, Zeichner (2005) called for a serious reconsideration of how educational researchers are prepared, including more funding for doctoral training programs for research in teacher education and post-doctoral opportunities to work with more experienced educators. Shulman et al. (2006) suggested that doctoral students in education who are preparing to be scholar practitioners should be prepared in fundamentally different ways from those who intend to devote most of their academic careers to research. Most of our doctoral students are exposed to a limited number of models of teacher education research, particularly in the areas of teacher and teacher educator learning.

In the introduction to this section, Sharon Feiman-Nemser concluded with a call for linking teacher learning to student learning and for better integration across programs of research. This is unlikely to happen unless researchers—whether in teacher education, student learning, organizational behavior, etc.—design programs of research that may incorporate, but go far beyond studies of their own classroom and students. Designs that involve researchers from different backgrounds who represent diverse theoretical orientations and teachers (at colleges and universities and in P-12 contexts) should work together to seek out funding to learn with one another and from one another’s expertise—bringing graduate students into the work in meaningful ways. Indeed, many of these graduate students will be former teachers and, if their expertise and experience is tapped, research designs can become richer, more productive, and more respectful of all who are
involved. Finally, given the issues of turnover I mentioned earlier, we may want to give more consideration to ways in which designs might anticipate some attrition, projects in which graduate students might engage in collaborative dissertations, cultures in which collaboration is expected and rewarded, and more publications (both in print and over the Internet) in which multiple perspectives, areas of consensus and dissent, and alternative interpretations are the norm.

The artifact from Dewey ends with the following plea, “The thing needful is improvement of education, not simply by turning out teachers who can do better the things that are now necessary to do, but rather by changing the conception of what constitutes education.” With respect, I would like to end with a paraphrase of this quote. The thing needful is improvement of educational research and the education of educational researchers, not simply by turning out graduates who can do better the things that are now necessary to do, but rather by changing the conception of what constitutes meaningful research on teaching and learning to teach. At present, many researchers are comfortable working in their disciplines and replicating their own experiences as they work with their doctoral students. This is reinforced in many institutions that demand individual accountability for publications because they know how to evaluate this form of productivity. It is further reinforced by the absence of funds or professional structures that encourage multi-disciplinary, collaborative, cross-institutional, and long-term research. Re-learning and changing what we know and do in relation to the study of learning to teach is an important agenda for those of us who are committed to the continuous improvement of teaching and learning.

INTRODUCTION

My academic life began at Antioch College in the late 1950s and early 1960s with a rigorous liberal education interspersed with co-op jobs in the real world. I proceeded to the University of Virginia as a graduate student in experimental psychology. Learning and motivation was my principal field of study, primarily in tightly controlled experiments with laboratory animals. Using college students as subjects and procedures that would today be called cognitive science, I also conducted studies on human learning, memory, and retention.

As a new professor, I advocated strongly in the faculty senate for the admission of more students of color, and as these arguments met with success, I was drawn into academic administration. Prevented by the demands of my work schedule from conducting my own laboratory experiments, I shifted to writing about the experimental literature, relying on review and analysis done in libraries and at home.

As a dean of liberal arts and sciences at three universities, and later as a provost at a fourth, I changed my research focus from psychology to education. I wrote about curricular innovations within U.S. higher education, and on comparative higher education, focusing on the German research university. In 1989, as president of the Council of Colleges of Arts and Sciences, a national association, I undertook a partnership with the American Association of Colleges for Teacher Education to explore innovations in teacher education through Project 30, a Carnegie-funded national initiative.

I offer these brief paragraphs of background to illuminate the values that inform my commentary on this section of the Handbook. Reading the framing chapters and artifacts, I was stimulated to think about three perspectives on research and analysis on teacher learning: normative, logical, and empirical. As I began writing, I recalled with sympathy William James’ observation in his classic 1890 text, Principles of Psychology, “I am often confronted by the necessity of standing by one of my empirical selves and relinquishing the rest. . . . All other selves thereupon become unreal, but the fortunes of this self are real. Its failures are real failures, its triumphs real triumphs . . .” (James, 1890, pp. 309–310).

Modes of reasoning

There are many ways to approach an analysis of teaching and the role of school teachers in bringing about pupils’ learning. I organize this body of work by its contribution to three modes of reasoning: normative, logical, and empirical.

For persons trained in laboratory-based science and quantitative methods, the term
“normative” usually means a central tendency in a population of measures around which variation occurs. Norm-referenced testing is an example of this use. In most educational discourse, however, the term normative has a technical meaning derived from the work of the sociologist Talcott Parsons (1937). This framework was most clearly brought into philosophical thought in the eighteenth century by David Hume, who contrasted descriptive statements (what is) with normative statements (what ought to be). Thus, normative refers to a mode of reasoning with values at its core. An example of a normative statement is that teachers should be competent, caring, and professional.

Logical reasoning is entirely dependent upon clearly stated and easily understood rules. With logic, knowledge is gained through the rational process called thinking and does not depend upon verification by observation. For example, if we know that a child cannot learn subject matter in the absence of that subject matter, we can deduce that if the teacher does not know the subject matter, the child cannot learn the subject matter from the teacher.

Empiricism refers to knowledge gained directly from observation based upon experience. Although essential to the procedures and reasoning associated with the scientific method, empirical knowledge by itself is not sufficient for science, which also requires systematic observation, usually in the form of designed experiments. Empirical reasoning can derive from qualitative methods, as in the examination and subsequent rating of portfolios of student work, or from quantitative methods, as in counting the number of arithmetic problems correctly solved by one student compared with other students.

Applying the modes to educational literature

Normative and logical conclusions could be subjected to empirical verification, but for many important purposes do not need to be. For example, we might choose to define successful teaching empirically as public evidence of student learning attributable to the teacher. Because this empirical definition has face validity in that most observers agree with it, I use it as a first screen when asking whether we have empirical evidence to support an assertion in the teacher education and teacher learning literature.

Now consider a normative proposition with which virtually everyone would agree: teachers should not abuse students. Conceptually we could imagine an empirical verification of whether abusive teachers are successful by measuring the learning of students assigned to abusive teachers in comparison with the learning of students assigned to non-abusive teachers; however, such a study is ethically unsupportable and in most places illegal. Many normative propositions are of this type, i.e. they define a threshold ethical context that overrules any empirical considerations.

The same arguments apply to most logical arguments, as illustrated in the proposition that teachers charged with teaching a subject matter domain should know the subject matter domain. Although many normative and logical propositions do not require empirical validation, empirical investigation often reveals matters of immense importance to the field of teacher learning, even when logical or normative arguments are seemingly very sound.

Consider the case of teacher subject-matter knowledge, for which we have established a logical foundation. In the domain of mathematics, there is compelling empirical evidence that student learning increases with the mathematical knowledge possessed by the teacher, but only up to a certain point, after which puzzling complications ensue. In an empirical study on a national longitudinal database (Monk, 1994), the number of college-level courses taken by the teacher served as the measure of mathematical knowledge, and scores on the National Assessment of Educational Progress provided a measure of
student learning. Student learning of mathematics indeed increased with the number of courses taken by the teacher, but only up to an asymptote of about five courses. A second empirical study by Rowan et al. (2002) indicated that students taught by teachers with advanced degrees in mathematics learned less than those taught by teachers who had taken fewer courses in mathematics.

These findings are important in understanding the nature of teacher learning as it relates to student learning, but they could not have been persuasively revealed by logical argument alone. Empirical study was essential. Furthermore, these empirical findings call into question a normative assertion that teachers improve their teaching of subject matter by completing advanced academic work in the field of study they will be teaching. The findings do not necessarily contradict this assertion, but they suggest that important qualifications, based on empirical investigation, may be needed before we can determine how to qualify the assertion.

Empirical investigation can also reveal startling findings that may revolutionize a field. A vivid example is the progress made by medical science in the nineteenth century in developing the germ theory of disease (Ewald, 1994), which many regard as the most important contribution by science to the welfare of people. The critical breakthrough, pioneered by the work of Louis Pasteur, came in the early twentieth century and led to universal adoption of “scrubbing up,” the practice of vigorous washing of hands before a clinical intervention. This simple practice immediately caused human mortality to plummet and life expectancies to increase. We now understand that germs cause disease, and that scrubbing up eliminates unseen microbiological vectors. The huge leap forward in saving lives was made possible by careful empirical investigation. Are such prospects possible for teaching? A persuasive answer depends on the kind of empirical inquiry that is now in its infancy in the field of teacher education and teacher learning.

Sensing a historic shift

Sharon Feiman-Nemser’s lucid introduction to this section on teacher learning implicitly highlights my reading that the field of teacher education and teacher learning is deep and rich in normative and logical reasoning, but shallow in empirical knowledge. As Borko et al. (2007) point out, teacher education is a relatively new field of study and it is very expensive and complex to design and carry out the kind of empirical studies that would benefit the field. Although this is an accurate assessment, the current historical moment is driven by political, social and technical factors that now favor sound empirical research.

Advanced societies are passing through a revolutionary turning point. In 1910 the U.S. census found that 50 percent of adults reported that they had completed more than eight years of schooling. By 1968 more than 50 percent of U.S. adults reported that they had completed more than twelve years of schooling. The effects of this aggregation of intellectual capital in the late twentieth century is being felt dramatically in all sectors of the economy.

New knowledge-based industries such as information, technology, and services are producing wealth at a rapid pace. The mainstays of the U.S. economy formed more than a century ago such as agriculture, manufacturing and heavy industry now increasingly characterize the economies of developing countries. High-wage low-skill jobs are emigrating out of the U.S., and are being replaced within the U.S. by new jobs requiring relatively high levels of skill and education. Since these deep shifts in our underlying political economy are occurring in all advanced societies, the U.S. now competes with
others for educated workers. These forces are the principle drivers behind today’s pervasive standards-based pressure on schools and teachers. They are more likely to increase than to recede in the near future.

We have also seen a dramatic increase in physical technology primarily through computers, and in intellectual technology through advanced statistical analytic methods. We now have the capacity to store and sort very large quantities of numerical data in very little physical space and to retrieve information from these data warehouses with relative ease. The introduction of widespread mandatory statewide tests in the late 1980s, coupled with the capacity to store information, made possible the accumulation and management of longitudinal databases that linked test scores of individual students with the specific teachers who taught them during the preceding year. Researchers skilled in statistics began to refine hierarchical linear models to look at the relative contribution to student learning, as measured by standardized tests, of various factors in schooling. Thus, empirical methods led to now widely discussed value-added assessment measures and to the increasingly accepted conclusion that teachers are the most important school-related factor in producing student learning.

We are at a very early stage of accommodating these advances. Statistical techniques, more powerful than any before them, nonetheless remain at a primitive stage of development; measures are often taken from tests with unknown or unsatisfactory psychometric properties. We have not yet widely applied broader and more authentic assessments. Given the inexorable pressure from the society at large for improvement of academic performance by the nation’s school children, as reflected in public policy, the time is ripe for significant government investment in educational research. The research community in the field of teacher education and teacher learning may be on the verge of an extraordinary opportunity to find the financing and conditions for research that will greatly expand our empirical knowledge.

The framing chapters

The chapters by Rodgers and Scott and by Rosaen and Florio-Ruane each reflect normative traditions within the profession. Each chapter also acknowledges the lack of empirical validation.

Proceeding from an insight-based tradition within clinical psychology, Rodgers and Scott state at the outset, “We hope that the introduction of a psychological frame will move the field of teacher education towards more empirical work in the development of self and identity in learning to teach” (p. 733). They conclude with the observation, “Clearly, what is still missing from the literature and the field is empirical work that seeks to better understand the role of psychology in teacher education” (p. 752). The chapter ends by asking the question, left unanswered, that is my primary filter for determining whether successful teaching has occurred, “What is the impact on [the teacher’s] students’ learning?”

Rosaen and Florio-Ruane state in their introduction, “We . . . call for empirical study of the alternative metaphors for designing and redesigning teacher education offered in the chapter . . .” (p. 708). In the concluding section they write, “. . . research on metaphors that reflect teachers’ conceptions of teaching and sense of self provides a foundation for . . . empirical work” (p. 726). The authors then pose a series of questions about teacher learning that could be answered by empirical investigation, such as, “If teacher candidates have opportunities to investigate metaphorical language as part of study groups comprised of experienced teachers and teacher educators, what do these activities help novices notice and pay attention to?” The ultimate empirical question of what
impact such education might have on the learning of these teachers students is not raised here.

Conspicuous in these chapters is the lack of empirical grounding for the ideas expressed. I have identified student learning as the critical dependent variable in studies of teacher learning and teacher education. What normative studies, such as those cited by Rodgers and Scott or Rosaen and Florio-Ruane, contribute is a strong theoretical framework for developing a set of independent variables. Until these independent variables have been connected to credible measurable dependent variables, they remain untested hypotheses joining others in a long queue of prospects for scientific examination.

Westheimer’s chapter on learning communities surveys a wide research literature that focuses on empirical outcomes. For example, Westheimer cites a survey of four studies that show the effects of professional learning communities on a wide variety of dependent variables: “reduced dropout rates among students, lower absenteeism rates, academic achievement gains (as measured by standardized tests) in math, science, history, and reading, and reduced gaps in achievement gains between students of varying socio-economic backgrounds” (p. 761).

Westheimer’s chapter also illustrates the tension between deductive approaches to collecting data and inductive approaches. Deductive reasoning involves working from a set of theoretical suppositions, and then designing data collection and analysis procedures to test them. In such a deductive mode, Westheimer asserts, “Highly restrictive, state-level curriculum frameworks, standards-based evaluations, and high-stakes testing for teachers and students can severely curtail new teachers’ capacities to teach as a community of colleagues . . .” (p. 771). No citations of empirical evidence are provided in support of this statement. Later, he cites a non-empirical speculation “. . . that matters of time and money are likely to be obstacles to community, particularly in low-income and understaffed schools” (p. 772). The theoretical framework informing these statements could be subjected to empirical test.

Inductive reasoning asks questions in the reverse order. For example, in a set of well-conceived studies, Springboard Schools first identified sets of schools matched on several variables, including low socio-economic status, where one set had shown a rapid trajectory of strong improvement and the other set had not (Oberman, 2005). The question for the investigators was: what conditions differentiated these schools? The overriding common difference was the development in the high-performing schools of professional learning communities. Every one of these high-performing schools was characterized by low degrees of time and money and all were in precisely the kinds of public-policy environments that Westheimer speculates would curtail capacity to teach as a community. Thus an inductive approach built from the ground up on empirical observation creates what appears to be an insurmountable challenge to the hypothetico-deductive reasoning stemming from a popular but untested theory.

The artifacts

The artifacts are rich in normative reasoning and they also reflect a deep understanding of the value of empirical evidence.

Lucy Sprague Mitchell’s inspiring, hortatory essay introduces empiricism in the very first paragraph, “So it is with a long-term experiment. It is only later when one can study the day-by-day records with a detached attitude that one can get a total picture. That is the reason for keeping records—to have something more reliable than memory as a basis for analysis” (p. 800). With respect to the dependent variable of student learning, Mitchell writes that her curriculum “. . . was based on two fundamental concepts—what
children are like and what subject matter, experiences, and activities best further their growth” (p. 806). She concludes her essay by again stressing student learning, “Every Workshop teacher we met was bubbling over with some tale of ‘what her children had done’ ” (p. 807). We see in this enthusiastic pioneer the reliance on empirical observation of student learning that was, in fact, what made her successful.

Dewey’s dense, tightly interdependent rhetoric builds a convincing case for thinking of teaching as clinical practice, and for the development of clinical practice through guided and reflective experience. Writing about student teaching, he recommends that “... the wise employ of this short time is in laying scientific foundations” (p. 788). He stresses that the artificiality of practice teaching makes the situation unreal for teacher candidates in contrast with the teacher candidate who “... has to build up and modify his teaching plans as he goes along from experience gained in contact with pupils” (p. 789). With respect to the dependent variable, Dewey insists upon “... the stress laid upon a certain end, namely growth or development ...” (p. 793). In a prescient observation, he says that a science of teacher learning demands “... consecutive and longitudinal consideration of the curriculum of the elementary and high school rather than a cross-sectional view of it” (p. 796). With Dewey, the necessity of an empirical orientation arising from direct experience is never in doubt.

Berliner’s now classic account of his research into the difference between novice and expert teachers continues to be valuable in many ways. It is, of course, empirical in that it compares and contrasts the clinical practice of beginning teachers with those of more experienced ones. His work demonstrates convincingly how qualitative rather than quantitative dependent measures can be empirical, systematic, and productive of reliable new knowledge. Lending great persuasiveness to his arguments is his ability to frame his findings against a large experimental literature of novices and experts in domains far removed from teaching. With respect to the critical dependent variable, Berliner’s findings are consistent with Mitchell and Dewey in pointing to student learning as the key measure of teacher quality. Berliner writes of experts, for example, that their teaching is “... primarily for growth and improvement rather than for sorting children out along an ability continuum” (p. 816). His studies are, like those of Springboard Schools, inductive rather than deductive. Berliner did not begin by attempting to prove a hypothesis derived from theory, but rather proceeded by careful observation of teachers differing along a continuum of low to high experience/expertise and let the empirical outcome dictate his theoretical considerations. Although this line of research outlines for us what the goal of teacher learning might look like, it does not tell us how to help novice teachers learn to be expert. It would be immensely valuable to replicate this line of work today, when we can use the technologies associated with value-added analysis to identify empirically highly effective teachers and contrast their clinical practice with that of novice teachers and experienced but low effective teachers.

Summary and conclusion

I have described three perspectives for approaching the research literature on teacher education and teacher learning. Normative reasoning is built upon values and describes what the enterprise of teaching should be. Logical reasoning ensures that a system of propositions about teaching is internally consistent. Empirical reasoning is dependent upon reliable observation of publicly observable events, and is usually advanced by careful measurement and quantitative analysis. Normative propositions can be valuable in their own right and need not always be validated empirically. Empirical validation is rarely necessary for logical propositions, since each proposition can be rationally
determined from other propositions. Yet science cannot advance without empirical study. We cannot confidently determine a responsible program to ensure teacher learning without a solid empirical foundation.

The literature of teacher education and teacher learning is richly endowed with normative and logical argumentation, but empirical evidence to support a program of teacher learning is scarce. The richness of the normative literature ensures a plenitude of independent variables that might be employed in empirical study. The essential and necessary dependent variable to employ as a measure of teacher quality, and thus of teacher learning, is student learning attributable to the clinical practice of the teacher.

We are entering a historic period in which it may be possible to gain financial and academic support for rigorous high-quality empirical studies that advance the field of teacher learning. We have physical and intellectual technology that is far superior to any available even in the recent past. Thus there is good reason to resonate with the optimism expressed by William James that our empirical triumphs will be real triumphs.

REFERENCES

When we were invited to comment on this section of the Handbook of Research in Teacher Education, we were pleased with the opportunity to respond to the powerful words of this diverse group of educators. It gave us a chance to reflect with a historical lens and an eye to the future on a topic that has engaged us for over 25 years—the topic of teacher learning.

What we value most about this collection is that each chapter emphasizes the intellectual nature of teaching, the prime importance of subject matter, the importance of understanding the student’s mind and psychology, and giving teachers the opportunity to develop expertise in the company of other teachers. These works honor the layers and levels in teaching and learning to teach—weaving the recognition of complexity and valuing expertise—and realizing that all ideas about education must be nested in the culture of teaching and schools. Each chapter celebrates John Dewey’s idea that we must prepare teachers to be “students of teaching” and, as the chapters make clear, it is at our peril if we do not create a teaching force of thinking, critical, highly intellectual and competent teachers with strong teacher identities. While the artifacts are mostly historical, and the three chapters present their ideas from a more “modern” perspective, they all demonstrate that, in the field of education, the difficulties and challenges faced by teachers and learners have not significantly changed in the past 100 years.

If one message connects all six pieces, it is that very little of what we call “deep learning” can occur without intellectual community. Joel Westheimer, reviewing the research of historians and sociologists who have examined teaching over the last century, says straightforwardly that the culture of teaching, both in the past and currently, has worked against creating this intellectual community. Too few teachers, he argues (echoing our own experience), are adequately prepared to learn from one another, and too few schools create the conditions where learning from colleagues might be possible.

Reading these chapters brought to mind the process of discovery we engaged in when, in 1985, the two of us formed a teaching partnership which led to the formation of the Learning/Teaching Collaborative—a collaboration among Boston and Brookline, Massachusetts public schools and Wheelock and Simmons Colleges—one of the nation’s first professional development schools. We were fourth grade elementary school teachers, examining our professional lives and practice, and by extension, the culture of schools and schooling.

Being acutely aware of the debilitating norm of professional privacy and lack of collaboration that surrounded us as classroom teachers, even in the “congenial” school culture in which we taught, we sought structures that would help us address what we saw as fundamental weaknesses. The life of the classroom teacher with its inherent isolation
supported neither collegiality nor intellectual stimulation. We were concerned with the one-step nature of the teaching career, a major factor in the deteriorating quality of student teachers now that there were so many options for educated women in the workforce. We were troubled as we watched children with learning problems—those who could least handle a fragmented day—taken out of the classroom for longer and more frequent periods of time. Working collaboratively as co-teachers who taught in the same classroom, we began to compile a list of things that needed change. We soon realized that we were looking at a blueprint for educational reform.

With a group of teacher colleagues we studied the “greats,” starting with John Dewey. His ideas helped prepare the philosophical foundation for our school/college collaborative where we wanted to create a new culture of learning—one in which we were all “students of teaching.” According to Dewey, “. . . unless they [teachers] continue to be students of subject-matter, and students of mind activity . . .” and unless “. . . a teacher is such a student, he may continue to improve in the mechanics of school management, but he can not grow as a teacher, an inspirer and director of soul-life.” (Dewey, 1976) We agreed with Dewey, and through our collaboration and our efforts to improve our intellectual lives as teachers, we proved to ourselves and others that teaching could and indeed must be a profession in which growth and learning on the part of the teacher must parallel the growth and learning of children.

We wrote and published papers, and attempted to deliver our message in many venues. Education Leadership rejected one of our first articles because they “already had an article in that issue by a teacher.” A respondent at an AERA session commented on our presentation by characterizing us as “the girls from Brookline with laudable goals.” Many thought our ideas were too radical. Others questioned our credentials. We were only teachers. Who were we to suggest these reforms?

But thanks to a convergence of forces, notably the perseverance and the power of working collaboratively, the support of our principal Jerry Kaplan, and the invaluable assistance of Karen Worth, a professor at Wheelock College, The Learning/Teaching Collaborative eventually took shape and grew (Troen and Boles, 1994). The overarching goal of this collaborative was to create new professional roles for teachers while providing them with the opportunity to continue teaching in their own classrooms. There are four components to LTC: (1) a collaborative school-based model for pre-service teacher preparation; (2) team teaching; (3) integrated delivery of special education services; (4) alternative roles for teachers as part of the school day, utilizing what we called Alternative Professional Teaching time (APT). This team-teaching model altered the organization of instruction, mainstreamed special needs children, and created new professional roles for classroom teachers in research, curriculum development, and teacher preparation.

At the heart of the Learning/Teaching Collaborative is the continuum of learning to teach. Novices are inducted into the culture of the team and veterans and novices alike make their teaching practice public. This context of teacher learning, woven through and across levels of expertise and knowledge, provides rich intellectual excitement. All are involved in the study of teaching—veteran learning from novice, novice learning from veteran (Troen and Boles, 1997).

Joel Westheimer emphasizes that the culture of teaching currently and in the past has worked against creating this intellectual community. Our objective was to change the culture of schools and schooling, and we therefore set out to create a community of learning. Three over-arching themes in the chapters and artifacts that make up this section echo the beliefs that became the foci of the Learning/Teaching collaborative:
The historic chapters agree on these points: Teaching is complex intellectual work that cannot be learned during a short internship, and teaching learned in collaboration with colleagues is richer than isolated learning. There are increasing levels of complexity to teaching and teachers go through stages toward mastery; but they are always students of teaching.

Lucy Sprague Mitchell addresses all three themes in Chapter 15 of her book, *Our Children and Our Schools* (1951) in which she describes how she used her Bank Street Workshops with New York City public school teachers to move away from rote learning and into deep curriculum understanding. The stages from examination and experimentation to creation of new curricula and intellectual teacher engagement is ably documented in her chapter—and was a significant aspect of LTC’s work with both novice and veteran teachers.

Mitchell speaks eloquently of teachers’ “growth toward professional maturity.” As she describes it, a “new curriculum,” replacing one that teachers had used for twenty years, was delivered to New York City public school teachers. It demanded newer methods without giving teachers adequate preparation, and thus the teachers maintained their earlier methods and used the newer methods as activities or add-ons while they continued to use the old syllabus for the real work of teaching. Mitchell notes “... these teachers felt little responsibility for studying their children and for planning experiences for them on the basis of such study. In some schools the teachers were told to be experimental, but few of them were or wanted to be.”

Once the teachers engaged in workshops, they began asking questions about the situation within which they functioned. Mitchell wondered, though, “How could they take responsibilities for educational thinking within their classrooms though they still remained on the lowest level as far as general decisions for educational thinking in the system were concerned?” Mitchell describes the slow awakening of the teachers to the thoughtful use of the new materials provided for them in the workshops—the progress from imitation of activities and the use of source materials to learn more deeply. As the group developed it became more interested in background content and teachers began building their own curriculum that met the needs of their own children. The teachers’ interest in how to acquire skill in the new techniques broadened to why these techniques helped children to healthy all-around growth.

In his chapter in *Effective and Responsible Teaching* (1992), David Berliner describes teaching and learning to teach as an ongoing process. He studied the elements of expertise, noting that expert teachers, just like experts in other fields, master the routine and develop automaticity “for the repetitive operations that are needed to accomplish their goals,” thus freeing them to focus on the intellectual facets of teaching. Expert teachers can interpret cues, recognize patterns and “instantaneously make sense of a field.” The ability of novices to perceive the same cues was limited. As Berliner concluded, “Learning that it takes considerable time to acquire competence in the pedagogical domain, let alone expertise, changes the way we think about support systems for the beginning teacher and the limits of teacher education programs.” We used the Learning/Teaching Collaborative model to help our pre-service teachers learn, as Berliner suggests, “... what experts attend to, what they find worth remembering, how they implement routines, and how they maintain a classroom that is considerate of their students...” at the same time developing a pre-service model that “... focused
on the acquisition of the pedagogical knowledge needed to teach both responsively and effectively."

The snapshots of teaching as intellectual work that we see in Dewey (1976), Mitchell (1951) and Berliner (1992) are repeated in the three new chapters. Westheimer’s review of the development of communities of practice reverberates with Mitchell’s workshop method—teachers thinking together—moving away from easy answers that respond to dicta from above. Westheimer does not ignore the tension that plagues efforts to forge communal identities without sacrificing individual teachers’ sense of autonomy. A major challenge for us in our work with the Learning/Teaching Collaborative was striving for a balance between collaboration and teachers’ individual needs. Westheimer’s question, “In what ways can collective projects among teachers further learning and development?” reminded us of our motivation to create Alternative Professional Teaching time, the most innovative of the Learning/Teaching Collaborative’s four components.

We designed Alternative Professional Teaching (APT) time to meet the teachers’ expressed need to supplement their classroom work with wider intellectual and professional responsibilities. It also provided the opportunity for teachers to learn new skills and gain expertise in an area that interested them. Some very sophisticated professional development was (and still is being) undertaken and accomplished within the APT structure, in part because APT allows teachers to engage in complex work of the sort that demands sustained, concentrated effort over time. For teachers who have APT, professional development is no longer conceptualized as “afternoon workshops on mandated topics,” which most teachers perceive as “deficit training” arranged by distant authorities. Rather, APT professional development work emerges from the interests and perceived needs of individual teachers and their students.

During their APT, some teachers conduct research to improve their own teaching or to test the assumptions of educational theory and practice. Others take on responsibility for teaching graduate student interns at the college and designing curricula that connect the theories and research studied at the college with actual classroom practice. A few develop, pilot, implement, and evaluate new curricula as part of town-wide curriculum initiatives, or develop curriculum with local educational consulting firms. As fully empowered partners in the team teaching process, they become improved classroom teachers and stronger advocates of education as well (Troen and Boles, 1996).

When we began to think about reforming the teaching career more than two decades ago, we based our ideas on some knowledge of theory and a great supply of empirical evidence. As we learned and worked for change, collaborated with the university and saw the value of theory, we recognized the importance of integrating theory and practice (Troen and Boles, 2003).

Lessons derived from the works of Dewey and Mitchell ring as true today as they did when they were written. Mitchell’s workshop program in New York introduced the intellectual side of teaching new curricula and replicated Dewey’s earlier drive to intellectualize teaching. Dewey and Mitchell highlight the importance of observation—teachers thoughtfully observing each other and learning from their work together. Berliner’s propositions reinforce the earlier norms set by Dewey and Mitchell.

In the contemporary chapters, the same themes emerge—Rodgers and Scott’s developmental look at the self resonates with the development of teaching skill emphasized in Berliner and Mitchell. How does this collection of essays inform our work in the twenty-first century? A beginning place is the focus on preparation of new teachers and the contexts in which they begin their teaching lives. What happens to new teachers when they enter teaching? What is the responsibility of teachers and teacher educators to create the communities so eloquently described by the authors of these six papers?
We recognize that none of these authors’ ideas will come to fruition without a supportive context, without colleagues and a professional learning community where novice and veteran teachers receive appropriate, ongoing support. We have learned—and research continues to confirm—that teachers cannot learn to teach well on their own. We know that new teachers need supportive, collaborative learning communities (Troen and Boles, 2003).

But we observe the new teaching generation with dismay. As veteran teacher educators, we see too many novice teachers who, after three years of teaching, feel they have mastered teaching and can move “up” into administration (Boles and Troen, 2004). In response, it is the responsibility of teacher educators to renew the intellectual underpinnings so eloquently framed by Dewey, Mitchell and Berliner, and so well described in the modern context by Westheimer, Florio-Ruane & Rosen, and Rogers & Scott. However, in a world bent on easily measurable accountability, on high standards that are difficult to attain (like the early twentieth-century curriculum that was poorly implemented in New York City, or the New Math that was ill-taught in the 1960s), there is the danger that we will ignore the lessons of these writers and thinkers and sacrifice the intellectual life of the teacher for the short-term gain of high test scores.

When policymakers ask what proof we have that any of these tools, methods, or theories made a difference in children’s learning, will we have ready quantifiable answers? This is the point at which it is tempting to say that in order to answer those questions, “more research is required.” But while research is always helpful, we don’t need more research to tell us what we already know. Nor do we need more research to tell us what we have been doing wrong, and will continue to do wrong, if we perpetuate a school culture that serves to defeat our attempts to create communities of learning. We know what to do right, and models for success have been created. We need only follow their lead.

45 The emperor’s new clothes

Do we really need professional education and certification for teachers?

Suzanne M. Wilson
Michigan State University

We live in an age of heated disputes concerning the quality and control of teacher education. Teacher educators, believing that teaching is work that requires substantial preparation, call for professional training, including both university coursework and supervised field experiences. Skeptics wonder whether there is any “there” there, whether the emperor—as it were—has any clothes. They raise questions about the content, control, and quality of teacher preparation, worried—as many people are in this age—about the monopolization of the enterprise. This debate gets labeled in many ways—alternative vs. traditional teacher preparation, professionalism vs. deregulation, for example—often in ways that obscure or oversimplify important differences. These questions—about quality and control—are perennial ones in the history of teacher education and certification, and it would be fitting for us all to be well versed in those debates.

The purpose of this section is to explore the history, content, and character of these oft-passionate debates about teacher certification. The reasons for these are many, as authors of the chapters and responses in this section clearly demonstrate. For one, schooling is very much a local enterprise in the United States, and choosing our teachers has also been a local enterprise. Everyone wants a say—parents, administrators, the public—and yet they have vastly different ideas about what matters. I have heard a state senator proclaim that her niece, a fine young woman who “loves children,” ought to be allowed to matriculate in a teacher education program, no matter her GPA. I have heard a father argue eloquently that all a teacher needs to know is the subject matter she is to teach, and at that keeping one chapter ahead of the children is okay.

The history of teacher education is also shaped by the field’s on-going attempts to claim professional status, and the second force at play in these essays is the rocky road toward professionalization, with its associated questions concerning the knowledge base of teaching and the technology of assessing that knowledge base. These twin desires for public ownership and professional discretion, not surprisingly, have resulted in a long history of bracing discussions about how, when, and under what conditions teachers should be prepared, certified, and licensed.

In addition, the authors here highlight the significance of an additional force that might best be understood as American skepticism, albeit of two different forms. The first is the argument for deregulation, which in education is most often experienced as calls for choice, charter, and vouchers. The sentiment here is that deregulation will lead to higher productivity and efficiency. Another form of skepticism might best be understood as the “critical turn,” which insists that we always ask, “Whose best interests are served by the current structures?” This form of skepticism asks questions about both the motivations of deregulation and the motivations for an autonomous profession for teachers and teacher educators.
These issues—public ownership, professional autonomy, and skepticism—are deeply rooted in political, intellectual, historical, cultural, and economic currents that run throughout U.S. history and culture, and the authors of the essays that follow illuminate how they have played out in the history of teacher certification. Michael Sedlak lays out the history of teacher certification and licensure up through the late 1970s. Sedlak’s account highlights the multiple actors who have participated in teacher certification over time: local ministers, school administrators, the emerging education establishment, and generations of (often) sharp-tongued critics. Sedlak also documents the history of the “technology” of teacher assessment, most notably the content and evolution of various attempts to examine teachers. Like most good historians, Sedlak reminds us that much of our current world is not really new, the questions and concerns that plague teacher educators and their critics today have erupted throughout the history of teaching and teacher education in the U.S.

David Imig and Scott Imig pick up the story line, and provide an insiders’ account of the last 25 years of D.C. politics around teacher education and certification. Theirs is a story of the contemporary struggles between teacher educators and their allies who are fighting the good fight for teacher professionalism, and the neoconservatives and Bush administration challenging the educational establishment’s right to that jurisdictional control. Their argument, that we have moved from “traditional certification” to “competitive certification,” provides us with a sense of the interconnected policy landscape in which teacher certification arguments play out, particularly with regards to the No Child Left Behind Act.

Wilson and Tamir propose a conceptualization of the battles over control that uses Bourdieu’s theory of social field, habitus, and capital. From this perspective, the social field of education is constantly being renegotiated by actors and groups intent on seizing or maintaining control. Bourdieu, building on the work of Aristotle and the medieval Scholastics, argued that each person or group has a habitus—a set of values, beliefs, dispositions, cultural norms, and the like—that to a large extent defines actions, or as Bourdieu would have it, “position taking.” Wilson and Tamir argue that a careful analysis of the criticisms leveled at teacher education might help the educational establishment, including teacher educators, interrogate our own habitus. By doing so, we might then be prepared to engage with those criticisms in productive ways.

Ed Crowe and Frank Murray offer thoughtful commentaries on the essays. Murray, a long time teacher educator leader, probes the question: Why is it so hard to find and retain over 3 million competent teachers for the purpose of assisting the nation’s schools in their mission? Crowe asks the fundamental underlying question: Is it a reasonable goal to position teaching or teacher education as profession? It is not a question we teachers and teacher educators often want to ask.

The section ends with a handful of artifacts that illustrate the dynamics of the debates that Sedlak, the Imigs, and Wilson and Tamir address. Included are excerpts from several important historical and current critiques of the system. For instance, Bagley’s (1919) account of teacher training describes a system with staggering low standards. Bagley, who understood teaching as an art, was deeply concerned that the poor investments in teacher preparation would lead to teaching becoming a mechanical practice, as more unqualified teachers entered the system with inadequate preparation. Bestor (1953a, b) offered another critical perspective. In On the Education and Certification of Teachers, he argues that we must make teacher preparation a university responsibility (not a college of education one). He argues also for limited preparation in pedagogy, deep exposure to the liberal arts and sciences, rigorous tests of disciplinary knowledge as a requirement for state certification, and an organized approach to field experiences.
Also included are past statements by teacher education “insiders” about the need to enhance the professionalism of teaching, including artifacts from meetings of the National Commission on Teacher Education and Professional Standards (NCTEPS). Peik (1948) spoke at the Bowling Green Conference, and provides an illuminating example of the interrelationships between the field of education, the professional preparation of teachers, and the assumed roles of teachers in preparing U.S. citizens to participate in the struggle for world leadership. Ralph McDonald (1956), then-President of Bowling Green State University and a leading figure in the professionalism movement, elaborates on the history and growth of teacher professionalism, from its inception as a vague idea to the organized meetings of the NCTEPS starting in 1946. We also provide two contemporary views of teacher professionalization, one by an insider, Allington (2005), and one by an outsider, Hess (2002). Allington argues that teacher education would be vastly improved if we ignored state and federal certification and accreditation policies: they often get in the way of high quality professional preparation. Hess also raises questions about the costs and benefits of teacher certification. His is a market-based argument, and he calls for competitive certification and “creative destruction” of policies and practices that compromise our search for high quality teachers.

Because alternative routes emerged as a policy solution to the problems recounted over and again in the history of teacher certification, we also offer several artifacts concerning alternative certification. Watts (1986) presents the educational establishment’s arguments against the perils of alternate routes and questions the two main arguments made by proponents of these reforms: (1) that there is a teacher shortage and (2) that traditional teacher preparation programs are preventing talented individuals from becoming teachers. Cooperman and Klagholz’s (1985) account of New Jersey’s alternate route illustrates how general discussions and debates over teacher certification evolved within the political boundaries of a single state. This piece in particular helps us understand how big ideas about teacher quality and teacher knowledge are transformed to the language of educational policy.

Finally, because teacher testing has been a central issue in discussions of teacher certification, we offer two artifacts from teacher assessments. Tests of teachers have evolved and changed, in part due to shifting notions of our collective sense of what a good teacher is, what teachers need to know, and what kinds of tests might be the best predictors of future teacher effectiveness. Here we offer examples from two different eras: Stone’s (1864) Complete Examiner and Fox’s (1982) National Teacher Examination.

Together, the artifacts and essays that comprise this section tell a story of struggle for professional status, for control, for quality. There are resonances across time, with similar promises and complaints pronounced by insiders and outsiders. Yet there is also progress, painfully slow at times. We may not have a certification and accreditation system that guarantees us high quality new teachers for all of our U.S. children, but the landscape of teacher education is different in 2007 than it was in 1849 and 1919. Continued—perhaps even more satisfying—progress can only be made if teacher educators and critics alike learn from the present and the past. Hans Christian Andersen’s The Emperor’s New Clothes, as a morality play, reminds us all that the smallest question can hold profound meaning. Sometimes teacher educators think that only scoundrels, like those pestering the emperor, ask the questions raised here—about professional autonomy and status, about the role of the free market in teacher certification, about the challenges associated with deciding what to test teachers on and how. Hard as it might be to acknowledge, it behooves us, for now, to constantly ask ourselves about why we want to don the clothes of a profession, and whether we have that right.

Competing visions of purpose, practice, and policy
The history of teacher certification in the United States

Michael W. Sedlak
Michigan State University

The history of the certification and licensure of teachers in the United States has always been contested: from the most intimate level, between employers and prospective teachers, to the broadest levels of national policy, between levels of government, between public and private organizations pursuing competing ambitions. Deciding who will be allowed to teach my child, your children, other people’s kids, is a struggle rooted in competing visions of America itself and is driven by questions grounded in national identity and personal aspirations: What role should education play in constructing a democracy? Why would we want our children to attend school? Where should authority over our children’s lives and futures reside? Who should we trust to care for our children? What, and how, should students learn in school anyway? The answers to such questions—inherently raised by the process of recruiting, selecting, and hiring a teacher—are even more important when the children attend compulsory, universal, tax-supported institutions.

Selecting teachers for one’s child, or finding teachers for other people’s children, has gone on since western Europeans began to migrate to this continent in the sixteenth and seventeenth centuries; indeed, the process was going on somewhere even before the First Peoples arrived. For centuries, finding teachers was primarily a matter of private and personal negotiation.

Entrusting one’s children to the care and instruction of others reflected concern with the sort of larger questions presented above; and had always led to thoughtful and skeptical decision-making. A well-known exchange between colonial leaders from the middle colonies and the Indians of the Six Nations reflected this concern. As part of a treaty signed in 1744, leaders from the Six Nations were invited to send young men from their tribes to William and Mary College. The Indians declined the offer, and replied as follows:

We know that you highly esteem the kind of learning taught in those Colleges, and that the Maintenance of our young Men, while with you, would be very expensive to you. We are convinced, that you mean to do us Good by your Proposal; and we thank you heartily. But you, who are wise must know that different Nations have different Conceptions of things and you will therefore not take it amiss, if our Ideas of this kind of Education happen not to be the same as yours. We have had some Experience of it. Several of our young People were formerly brought up at the Colleges of the Northern Provinces: they were instructed in all your Sciences; but, when they came back to us, they were bad Runners, ignorant of every means of living in the woods . . . neither fit for Hunters, Warriors, nor Counselors, they were totally good for nothing.
We are, however, not the less oblig’d by your kind Offer, tho’ we decline accepting it; and to show our grateful Sense of it, if the Gentlemen of Virginia will send us a Dozen of their Sons, we will take Care of their Education, instruct them in all we know, and make Men of them.

This touching, yet sassy, deflection suggests the depth of the meaning of decisions about who will teach what, and to what purpose, in our schools. White, European immigrants were also concerned about the purposes of education, and whenever possible they supported mechanisms to find and hire teachers who were properly fitted to instruct their children. Throughout the colonial period, until the early nineteenth century, schools served a fairly narrow but significant range of functions. From England, settlers brought with them an understandable preoccupation with their spiritual salvation, and very quickly enacted the sort of requirements that governed expectations of religious orthodoxy in their homeland. In the New World, they never actually replicated the dizzying policy shift that occurred in England between 1553 and 1581, when all of the Protestant teachers were replaced with Catholics, who were then replaced by Protestants following a regime change; and both were quickly replaced with an Anglican teaching corps several years later. But, in Massachusetts Bay, just a generation after the colony was established, the highest court—concerned as it was that youth be educated “not only in good literature but in sound doctrine”—recommended in 1654 that the selectmen who oversaw local schools rid their communities of teachers who were “lacking in faith and are scandalous in their lives and have not given satisfaction according to the rules of Christ” (Kinney, 1964, p. 39).

Like Massachusetts, most colonies authorized a variety of local actors—religious elders, prominent citizens, lay boards—to be responsible for finding and hiring teachers. Typically, these employers used informal approaches when making decisions about potential instructors. They relied on ministerial recommendations. They queried candidates about their beliefs and values. They assessed their physical strength and courage. They hired their relatives, with whom they were intimately familiar. And they occasionally tried to determine their potential teachers’ academic expertise, largely by examining handwriting samples and listening to prospects read homilies or passages from the Bible. Conducting penetrating examinations of academic competence were often less important than gauging the other qualities, however, particularly because the prevailing approach to teaching—memorization and recitation—demanded literacy but not much more than a shallow understanding of what we would call school subjects.

This pattern of individual negotiation in a private market proved to be an enduring model, if not always a fully satisfactory way of recruiting and employing the most desirable teachers. It lasted two centuries, through the first few decades of the nineteenth century. Gradually, this tradition was undermined by abuses of nepotism and the fallout from lazy or uneducated examiners, yes, but more importantly it was challenged by the emergence of a new sense of purpose for education, whose advocates could no longer trust the consequences of private arrangements.

An array of social, economic, and demographic changes converged over the first third of the nineteenth century to galvanize reformers around a new vision for education. Economic change—highlighted by blossoming industrial capitalism, the first wave of the deskilling of labor, and the emergence of an American working class—convinced prominent citizens, business leaders, and some politicians that it was essential to begin building a labor force with a new form of work discipline, respect for property, commitment to new definitions of time and punctuality. Urbanization—represented not simply by increasing population density but by residential segmentation and stratification and the
separation of home from work—led reformers to replace disintegrating forms of personal and neighborly social control with institutional supervision. And demographic change—symbolized by the arrival of the genuinely foreign Irish Catholic peasants—spurred civic authorities to establish mechanisms for intentional nation building and for developing common political and social values. Together, these dynamic changes demonstrated that there was considerable work to be done, and community and state leaders turned aggressively to the schools to undertake that work.2

These new social and economic ambitions for education demanded schools dedicated to expansive purposes beyond basic literacy and religious indoctrination. These new purposes would demand new forms of organization, curricula, and instruction. They would demand teachers with professional knowledge and commitment who were willing to invest in their own preparation, and able to contribute to what the reformers envisioned as an actual system of education.

The mid-nineteenth-century reformers moved to address the qualifications of the teaching force on several fronts. The most aggressive public policy actions focused on fashioning an embryonic certification system. Unwilling to tolerate the notorious abuses associated with local control and the “excesses of democracy,” and not content simply to recommend better tests, they moved over the second third of the nineteenth century to launch the process of centralizing the licensure process. Governmental authorities, occasionally at the state level, but particularly at the county level, began to seize control of the examination system.3

They found many weaknesses in the prevailing examinations. The idiosyncrasies of many local laymen, the educational reformers were convinced, posed the greatest problems with the tradition of teacher testing. The folklore of assessments included too many examples like that recalled by John Swett in his memoir of teaching in California. The president of San Francisco’s board of education himself—“a man of inordinate conceit”—prepared and administered a comprehensive examination. Swett reconstructed the geography section:

1 Name all the rivers of the globe.
2 Name all the bays, gulfs, seas, lakes and other bodies of water on the globe.
3 Name all the cities of the world.
4 Name all the countries of the world.
5 Bound each of the states in the United States.

He added that after the one hour allowed to answer these questions, some of the examinees were “still at work on the first question, some on the second question, a few on the third, and one on the fifth.” Years later, after digging the results out of the board of education’s archives, Swett learned that the board president issued a report indicating that “we all stood exactly alike, sixty percent” (Swett, 1911, p. 114). Sometimes examiners could not even answer their own questions. “What is the product of 25 cents by 25 cents,” a candidate in Indiana was asked. After he responded that he did not know, the examiner, who appeared “a bit perplexed,” said that he thought the answer “was six and one-fourth cents but he wasn’t sure” (quoted in Elsbree, 1939, p. 183; Vold, 1985).

Local examiners were also under extraordinary pressure to falsify examination results in order to guarantee teaching positions to well-connected community members. One test administrator from Ohio, who would no doubt find appealing the campaign to centralize control of the testing apparatus, testified to the personal vulnerability of local examiners. “Not infrequently,” he observed,
candidates who have made an exhibition of their ignorance and utter incapacity will importune in the most urgent and pathetic way for certificates. Local directors, sometimes, plead that a candidate be spared rejection with an importunity like that of Abraham when praying for Sodom. A brawny brother has, more than once, intimated that a sad retribution would . . . overtake the examiners if his sister should be without a commission; though the girl could not repeat the multiplication table, if it were to save her from the doom of Gomorrah.

(Fifth annual report [Ohio], 1858, p. 99)

Because examinations were historically private events, attended only by the candidate and the examiners, both standards and individual performances remained discreet and flexible, which appealed to supporters of the patronage system of appointments. Since private examinations were so easily abused, however, some community leaders called for opening the events to the public. In addition to calming fears of favoritism, public examinations could offer other benefits. In an era of unprecedented community boosterism, when one educational institution competed against another to improve neighborhood status and attract settlers, examining teachers and students in public could be an attractive mechanism. One advocate of public examination in New Jersey in 1850 asked, “why should there not be a county competition, to exhibit the best teachers, the best schools, and the best-educated scholars, with far more propriety than which county can produce the fattest hog or the largest turnip?” (quoted in Elsbree, 1939, p. 184).

Agents of centralization, who were committed to deepening and extending the functions of education, confronted the notorious tradition of local examinations initially by requiring county and even state officials to take primary responsibility for testing prospective and returning teachers. Ohio, for example, moved—somewhat prematurely it turned out—to have the courts appoint three “examiners of common schools” in every county to “examine and certificate teachers” (Kinney, 1964, p. 46). Other Common School advocates pressed for more rigorous and standardized examinations, and encouraged the production and distribution of more systematic tests of academic and even professional knowledge. There emerged a small industry in publishing collections of widely used questions for the new examining boards (and for prospective teachers to study and review for their upcoming tests). These guides typically included questions covering introductory to advanced content in the entire array of school subjects.

John Swett’s collection, which he released in 1872 to assist principals struggling to design productive questions for prospective employees, or even for inexperienced teachers needing to assess their own students’ knowledge, was typical. The section on arithmetic began with questions like “divide $7.00 by half a cent. Multiply $5.00 by $5.00.” It ended with more demanding questions like “find the greatest common divisor and the least common multiple of 18, 48, 72, 66.” His English grammar questions asked examinees to “write sentences to show the correct use of the verbs lie, lay, sit and set in the future perfect (second future) tense, indicative mode,” and “what do you mean by an idiom? Give an example.” A simple geography question asked for the “four leading exports of California,” while an advanced question asked “why is it warmer on the Pacific than on the Atlantic coast of the United States, in the same latitude?” His composition assignments were elaborate: the examinee was asked to write a two-page manuscript on subjects like the following:

Or

(all quotes from Swett, 1911, pp. 5, 18, 19, 38, 40, 50, 100, and 101)

The testing manuals also included sections on professional knowledge, which the county and state officials increasingly incorporated into the required examinations. Soon after the superintendents in Iowa’s schools gathered to release a statement indicting the state’s teachers for being “deficient in a knowledge of mind—its operation and how to control it,” the legislature amended the examination law to include the “theory and practice of teaching” (Aurner, 1918, p. 298). Maine’s examination in 1848, for example, asked candidates how they would deal with children who were “(1) obstinately disobedient? (2) physically and mentally indolent? (3) addicted to falsehood? (4) impulsive” (Maine School Report 1848, 57; quoted in Elsbree, 1939, 180)? One of the most famous collections of common questions, Isaac Stone’s The Elementary and Complete Examiner (1864), begins its chapter on professional knowledge by stating that “The principles implied in the foregoing questions [about academic subjects] will be of but little avail to Candidates, unless they have a good theory of imparting instruction; a theory which they can practice” (Stone, 1864, p. 200). His taxonomy of professional knowledge ranged from routine questions like “What can you say of the ventilation of the school-room?” to complex, demanding questions about motivating students, pedagogy, and discipline:

Is it wise or otherwise for a teacher to ask a mischievous or vicious pupil to do a favor for him?”
Should a teacher be held responsible for the intellectual growth of his pupil?
Which is preferable, the “pouring in,” or “drawing out process?”
What can you say of the relation of the teacher to the parents of his pupils?
State briefly your idea of the Science of Education.

(Stone, 1864, pp. 200–201)

Among many other topics, Swett’s anthology asked the following questions about the “theory and practice” of teaching:

What position do you prefer to have your pupils take when reciting?
For what particular offenses would you inflict corporal punishment?
What do you conceive to be the relative advantages of public and private schools?
What do you consider the aim of all educators to be?

(Swett, 1872, pp. 66–70)

In addition to standardizing the examination system, public authorities holding the new social vision for schooling also claimed that educators needed to become more professional and to have their knowledge, skills, and commitments developed through formal professional training. Historically, through the first half of the nineteenth century at least, the vast majority of teachers, few of whom taught more than a session or two, had little evident commitment to instruction, their pupils, or their employing communities. Teaching was largely a transient occupation, and probably no more than a handful possessed subject matter knowledge significantly greater than their students. There were few incentives for most teachers to invest in an extended academic or even
introductory professional education. The minority of schoolmasters who were dedicated, successful instructors, would have acquired their professional knowledge about organizing schools, motivating and disciplining students, and evaluating recitations, from the important manuals published for teachers, whose experienced authors often traveled to conduct seminars and workshops.\(^4\)

In order to address what they perceived as deficiencies in ambition, commitment, and skill, educational leaders at the county and state levels—from New England through the Midwest—called during the 1840s and 1850s for investing public resources in normal schools, which became the first distinct teacher education institutions. Historians have thoroughly reconstructed the origins and evolution of the normal schools and other local teacher institutes.\(^5\) I want to make several simple points about this important stage in the development of preparation and certification policy. The most influential state leaders who fought to create and sustain programs of professional education shared an expansive, liberal vision of the function of public authority, particularly the potential for schools to improve social, economic, and individual conditions. And they were convinced that much prevailing instructional practice could do little to enable students to attain the levels of civic awareness and industrial capacity that the future would need. Schoolmasters who simply listened to memorized recitations, or who disciplined students into submission and compliance (practices leaders believed were common, even at the most respected academies) were not prepared or even willing to consider far more ambitious pedagogical techniques. Horace Mann’s famous confrontation with Boston’s senior schoolmasters revealed his preference for more engaging instruction, as did his many reports on new techniques surfacing in Europe (Church & Sedlak, 1976; Rury, 2002).

Furthermore, in a struggle that would be echoed in the mid-twentieth century, normal schools competed with liberal arts colleges and in some regions even with secondary academies for market share. In an era when the educational ladder was overlapping and an array of institutions served young men and women between 14 and 21, advocates of embryonic liberal arts colleges objected to the creation and expansion of the normal schools and their desire not only to usurp the teach training functions of these other institutions, but also to provide greater opportunities for adolescents outside the large urban centers to pursue academic study. Herbst’s close analysis indicated, for example, that in western Massachusetts, Westfield Normal successfully competed with Mount Holyoke for young female students, and capitalized on its advantage as a public institution to attract students with lower tuition (Herbst, 1989, pp. 80–81).

The new professional education institutions were especially undesirable to those who held the traditional, narrow view of the limited function of education. Just after the moment of their creation in Massachusetts, for example, a political campaign erupted to eliminate the fledgling normal schools and to disband the state board of education. As Carl Kaestle and Maris Vinovskis noted in their study of this event, the challengers argued in their report that the “existing academies and high schools were ‘fully adequate . . . to furnish a competent supply of teachers.’ ” The opposition committee’s conclusion was rooted in a traditional view of educational purpose and operation:

> Considering that our District Schools are kept, on an average, for only three or four months in the year, it is obviously impossible, and perhaps, it is not desirable, that the business of keeping these schools should become a distinct and separate profession, which the establishment of Normal Schools seems to anticipate.

(quoted in Kaestle & Vinovskis, 1980, p. 218; see also, Kaestle, 1983)
This is exactly the attitude and perspective that Mann and his generation of policy leaders fought over the ensuing decades.

After mid-century, then, ambitious public educational reformers had begun to shift arrangements for recruiting and hiring teachers. They not only voiced their objections to the traditions of diminished expectations for schooling and local control of, and dissatisfaction with, “unqualified teachers,” but they were fashioning new policies—backed with unprecedented investments—designed to build a more standardized system capable of educating students for a new society and economy. They pressed for teacher quality policies that recognized and encouraged, if not always enforced, formal professional education. They launched an effort not only to elevate the certification process to the county and state levels, but also to expect and reward the possession of educational credentials. Over the latter half of the nineteenth century, this new pattern unfolded across the country. The balance between examinations and credentials fluctuated, as local authorities challenged higher-level officials by trying to exploit every opening in their state’s certification laws. But state after state followed the lead of California, which in 1863 was the first state to accept professional educational credentials in lieu of examinations. By 1900, 41 states recognized both normal school diplomas and credentials from four-year colleges as acceptable alternatives to tests. In New England, and the deep South, where the colonial traditions of local control through examination were the strongest, the process was bumpier, but the shift reflected a clear national consensus by the early twentieth century (see Sedlak, 1989).

Teachers themselves began to join these constituencies concerned about the professional stature of education, and especially those who were troubled by the inadequacies of existing recruitment and hiring practices. As the campaign to spread this new vision of educational purpose gathered momentum in the 1850s and later, individuals attempting to fashion teaching jobs into actual careers resented the assumptions of transiency and amateurism embedded in the prevailing hiring arrangements. They grew frustrated by annual examinations, unpredictable standards, and temporary certificates. As teachers became more committed to effective education, they also pressed for the de-politicization of hiring, since patronage systems appeared to undermine the meritocratic ethos that was building within the educational enterprise. Reformers and many teachers alike believed that, as schools would perform increasingly indispensable social functions (including resolving social problems and expanding economic opportunity), they should more visibly and explicitly reject all traditions and trappings of ascription and embrace more defensible, standardized, uniform, professional practices.

The next phase in the history of certifying and hiring teachers witnessed the accelerating dominance of the professional educational credential model, and the steady increase in the minimal duration of prerequisite study. Appointing individuals to teaching positions remained at the local level, of course, but states gradually restricted the pool of legal prospects. And states increasingly granted certificates on the basis of educational attainment rather than examination performance. By 1873, according to a leading analyst of this issue, policy makers were beginning to recognize credentials from normal schools as “professional licenses,” and several states were relying on them exclusively as the basis for certification. By 1897, 28 states accepted normal school diplomas, and by 1921 all but one state “recognized graduation from normal schools and universities as evidence of qualification for certification” (Cook, 1927, p. 3). By World War I, therefore, certification policies that bestowed licenses on the basis of credentials had become the rule nationwide.6

Despite the shift toward credentials in most regions, the examination tradition persisted in the South, where virtually every state continued to base certification on the basis
of test performance as well as professional study. In other regions, developments were mixed. In Indiana and Wisconsin, for example, centralization proceeded more slowly because of a reluctance to deploy the states' plenary power in education. Many states also continued to require examinations for high school teaching certificates. But, as a reflection of the increasing impact of normal school and university programs of study, these tests increasingly included questions drawn from studying professional education, including pedagogy, management, and educational history and philosophy.

The expansion of the credential model grew dramatically as graduates of professional programs assumed leadership roles in state departments of education. Small-state departments were among the most highly professionalized sectors of the educational enterprise, and their staff members often owed their positions to their educational attainment, or were willing to respond to the lobbying of the professional education institutions. Many of those who owed their positions to their credentials distrusted examinations and wanted to reduce their impact on licensing. As one commentator observed: “The evil attendant upon the examination system that had been perfected to determine detailed knowledge of academic subject matter led to bitter opposition on the part of those trained in the newer professional school” (Morrison, 1928, p. 49).

Professionally trained educators objected to the view that it took only subject-matter knowledge in order to teach effectively. They were familiar with the tradition of abuse that continued to plague examinations, and were distressed about the gamesmanship and shallowness that contemporary testing practices tended to encourage and reward. Furthermore, during the late nineteenth and early twentieth centuries, other, more prestigious, occupations were abandoning informal idiosyncratic licensing practices for standardized educational credentials. Many believed that professionalization itself demanded advanced, formal professional education, sometimes as a substitute for examinations, sometimes in combination. Regardless of the reasons (some of which were sincere, while others were flagrantly self-protective), the movement of professionally educated teachers and administrators into positions of system-wide leadership and influence further undermined the tradition of simply testing aspiring professionals.

Raising standards—by requiring professional education or by making the examinations more challenging and professionally relevant—undoubtedly resulted in much individual pain. Heightened standards were assumed to limit access to teaching opportunities, particularly by closing off the mobility of youth from rural backgrounds. Shortly after World War I, for example, the Illinois superintendent for public instruction received a letter from an exasperated woman who was attempting to return to teaching at 46 after her husband died. She had been granted a temporary “Emergency Certificate” because of a spot shortage, but was unable to get “a certificate without ‘Emergency’ written on it,” as she complained to—and pleaded with—the superintendent. The superintendent responded publicly to the letter in order to disclose the “strong appeals [that] can be made to the hearts of the certificating authorities and boards of education to relax or set aside the plain requirements of the law and to forget or subordinate the primal interests of the children who are to be taught.” He raised the question of certification standards, arguing that, in teaching, traditions of licensing had too often been rooted in earlier days when it was common to select men who had some disability or handicap, “on the assumption that school teaching was an indoor occupation and required the minimum of physical health and completeness.” The situation had changed, he commented, particularly since young middle-class women with strong academic qualifications began seeking and securing teaching positions:

Most young women, looking forward to teaching school, try to prepare themselves
In a very conscientious way for the work. There still remains, however, the old idea that in selecting a teacher certain charitable ends should be kept in view. Every attempt to lift the scholastic and professional requirements for teachers in Illinois has met with the statement that higher standards will keep the poor man’s daughter from teaching, overlooking entirely the fact that there is much greater charity, much more of the milk of human kindness, much more of sound common sense in trying to secure for poor men’s children the very best teacher that can be had rather than in trying to get for a poor man’s daughter a job for which she is not qualified.

(Ed., 1924, p. 761)

In sum, the enterprise of licensing teachers had changed in a variety of ways during the half-century prior to World War I. The practice of bestowing certificates to candidates on the basis of professional education rather than examinations exclusively was dramatically expanded. Whether through examination or educational attainment, certification was becoming centralized at the state level. The county superintendencies that had moved certification forward during the mid-nineteenth century were declining in power as states sought to tighten controls over the licensing of teachers, and because of a general movement toward centralization and standardization. This trend is evident in the table presented below, which indicates a progressively rapid process of centralizing certification to the state level (Cook, 1921; Cook, 1927; Cubberley, 1906; Jackson, 1903). Local certificates were also a victim of the effort to improve “reciprocity” that built during the late 19th century, especially in the North where groups of states made elaborate compacts to recognize one another’s certificates (Barrett, 1902).

And, the number of categories of certificates increased dramatically. Differentiation of professional roles in schools contributed fundamentally to this process. The growing public and professional fascination with precision, order, and “scientific” classification schemes of all kinds undoubtedly contributed to this explosion as well. The annual, temporary certificates common during the mid-nineteenth century were replaced in some places in the twentieth century by permanent or life certificates (typically based on educational credentials).

Significantly, virtually all varieties of educational “progressives” in the late nineteenth and early twentieth centuries agreed with these changes in certification policy and practice, and many of the larger organizational reforms that were grounded in a new sense of purpose for education. The more liberal “pedagogical” progressives, who supported comparatively radical changes in methods of teaching and curricular design, were joined by more conservative “administrative” progressives, who shared enthusiasm for modernizing the curriculum, but also were committed to expanding state and county authority over local schools and deepening the hold of scientific rationalism over the schools.7

Although for possibly different reasons, both groups largely endorsed professional education for teachers and administrators. Pedagogical progressives wanted to reform teaching practice so that student learning would be deeper and more powerful than they perceived it was under the tradition of superficial factual memorization, which remained common into the twentieth century. They wanted students to be more engaged and personally connected to “relevant” curricula, and were distressed with the continued dominance of classical studies, especially at the high school level. They believed that the militantly classical curricula and teaching style of the nineteenth century was “undemocratic,” and ill-suited to the diversifying profile of students that was enrolling in schools, particularly the waves of immigrant students, children of color, and working-class adolescents who were converting the high school into a mass institution. They pressed for preparing and hiring teachers who were dedicated to modern, diversified
curricula, and with the depth of understanding of child development and psychology, repertoire of methods, and social vision to bring the schools into the twentieth century.

Administrative progressives aggressively challenged many manifestations and idiosyncratic practices of local democracy—the ward system of electing school board members insistent on representing neighborhood interests, unqualified personnel who found their way into teaching assignments through dubious routes—by “taking the schools out of politics,” expanding the appointment of “experts” in administration and governance, and centralizing control under the mantle of science wherever possible. They also embraced curricular modernization and differentiation—through the creation and rapid expansion of the practical arts and vocational classes—to increase efficiency and economic productivity. Concerned about the emerging disconnect between traditional schooling and the modern industrial and corporate economy, these progressives held a larger sense of social purpose for education. Their vision—particularly those associated with the campaigns to create the junior high school and to transform secondary education—focused more on economic efficiency and vocational adaptation than the liberal progressives, who sought more individual opportunity. But both groups envisioned an ambitious, socially indispensable role for schools, a vision that depended on teachers with both academic and professional knowledge and commitments, whose abilities would be guaranteed through expansive state certification policies.

Conservative educational scholars and administrative reformers were troubled by the residual—if declining—use of examinations to identify and hire prospective teachers and pressed to base eligibility to teach on higher educational attainment. The transformed high school obviously demanded significantly stronger academic credentials, they observed, and even the emergent efforts to individualize and personalize learning in the elementary school were revealing the weakness of typical teacher tests (Dutton and Snedden, 1908). In his systematic study of certification and licensure, E. L. Cubberley of Stanford University, the most influential educational reformer of the early twentieth century, argued forcefully that secondary teachers needed “advanced training beyond that given in the high schools or normal schools.”

Cubberley argued that this advanced education could never be “enforced by means of a written examination.” The only “safe way” of securing this level of talent, he continued, was to “impose a definite educational requirement, such as graduation from a college of recognized rank,” as a prerequisite to certification. “Either certain work or courses in education,” he added, “should be required to be taken as part of the college course” in order to guarantee the “strictly pedagogical part of the preparation” (pp. 60–61). Cubberley endorsed this expectation for all certificate levels. Even the work of the “kindergarten is special and requires special training,” he stated, and endorsed “graduation from a reputable kindergarten training-school, or from the kindergarten department of a state normal school” (pp. 62–63). He held up California’s recent elaborated state certification code as a model, but admitted that few other states matched this vision in 1906.

Cubberley’s disappointment about the state and pace of centralization and elevated
academic standards for teacher certification resonated widely. Reformers across virtually all regions launched intense campaigns to convert their state policies in the direction of the California model. The following two tables reveal the consequences of their actions. First, the number of states requiring a bachelor’s degree for teaching accelerated rapidly after 1910.

As is evident, the spread of graduation requirements for certification spread most rapidly during the 1920s, a period of rapid standards-raising that occurred during a time of teacher shortage. The following table indicates the parallel expansion of professional studies at the four-year degree level (developed from Kinney, 1964, p. 83).

California consistently set the pace for “progressive” licensure. In that state, the certification law of 1893 established a minimum of graduation from an accredited university with at least 12 semester hours in pedagogical courses for a high-school teaching certificate. This ambitious requirement was increased even further in 1906, when the state board of education restricted secondary certificates to those with one year of graduate credits (with a few subject-field restrictions, all of which were removed in 1928) (Frazier, 1938, p. 304).

The timing of events in many states in the North, East, and West lagged behind California, but paralleled those in Michigan. Responding to pressure from the Michigan State Teachers Association, the state moved to adopt a normal school graduation standard for elementary teachers during the early 1920s. At the secondary level, the North Central Association pressed the state to move beyond a simple baccalaureate requirement and endorse its proposal to redefine a “qualified” teacher as one who was certified to teach—and who taught—only in the subject(s) of his or her collegiate major or minor. The state gradually expanded the professional school requirements and standardized them, so that by 1925 they had begun to assume the dimensions that would serve throughout the twentieth century (Goodrich, 1928, p. 548; Davis, 1924b; Stinnett, 1969).

Southern states moved somewhat more slowly to raise standards of entry by centralizing the certification process and by abandoning the examination tradition for educational credentials. The region began to endorse normal school preparation after the turn of the century, but apparently imposed a relatively non-aggressive policy of “advising” attendance. Some states, like North Carolina, which held on to its examination system until the 1920s, attempted to strengthen the professional education of teachers by requiring them to attend two-week county institutes, and promoted summer-school
classes for teachers (Stinnett, 1969, p. 398; ed. 1922, p. 304). Teacher training institutions were allowed to develop their own approaches to professional education with virtually no interference from the states. Over the course of the 1920s, standards in professional education throughout the South shifted, generally from summer-school and extension classes, brief institutes, and reading circles to formal pre-service educational programs (Stinnett, 1969, p. 398). Pressure for conformity in that region came from the professional education establishment rather than from state governments.

In addition to strengthening the expectation of formal professional education, the standards-raising movement of the 1920s began to articulate and enforce regulations concerning the content of teacher-education programs. The package of courses in social and psychological foundations, generic and subject matter pedagogy, and practice teaching began to assume the proportions that would constitute the preparation model until the wave of professionalization reform of the 1980s.

Raising standards had an immediate impact on the professional qualifications of the teaching force. A survey conducted early in 1925 revealed the extent to which states were approaching “the ideal of a trained teacher in every classroom.” Between 1920 and 1925, for example, a number of states made substantial progress in raising the proportion of teachers with at least two years of normal schooling: North Carolina’s “trained” teachers increased from 18 to 40 percent of the total force; Pennsylvania’s grew from 50 to 78 percent; Oregon’s jumped from 54 to 70 percent; and Wyoming’s rose from 24 to 40 percent. The study’s author attributed the improvement to “the influence of vigorous state policies” designed to raise certification and entry standards in teaching (Bagley, 1925, pp. 113–114; Morrison, 1928, p. 49; Rosier, 1925; Dynes, 1931; see also important surveys: Hood, 1916; Learned & Bagley, 1920; Cook, 1920; Deffenbaugh & Ziegel, 1932; Evenden et al., 1933; Siedle, 1934; Slaughter, 1960; LaBue, 1960).

Once the professional education model was established and diffused nationally as the dominant route into teaching, the place and nature of examinations shifted considerably. They did not disappear entirely, but over the first third of the twentieth century they came to perform very specific functions for the educational enterprise. No one seriously advocated using them as a general mechanism for controlling entry into teaching. And no one believed that they could be used for bestowing general certificates, even under most emergency conditions. Virtually every analysis of the teaching force—its labor market and its demographics—elaborated the litany of familiar complaints about the examination tradition. Tests encouraged substandard preparation; examinations were “undependable in predicting teaching success;” and, tactfully, “undesirable local pressure for unmerited certification is often exerted when abuses in examinations are possible” (Anderson et al., 1937 and 1934; Parkinson, 1932, pp. 422–448; Carnegie Foundation for the Advancement of Teaching, 1932, pp. 56ff.). They continued to be used in some rural districts, nevertheless, and occasionally for granting temporary access to teaching specific subjects, like music or drawing.

The most interesting and visible movement on the testing front before the 1980s surrounded the creation of the National Teacher Examination in 1940. Examinations could play a useful role in hiring and promoting teachers, argued critics who condemned bestowing initial licensure on the basis of a single test. Especially during the 1930s, a time when there was a surplus of teachers, pressure mounted to create an examination that would help popular districts to differentiate among many well-qualified applicants.

The National Teacher Examination was rooted in a series of three testing projects completed in the late 1920s and 1930s. The first developed an instrument to assess the professional and content knowledge of elementary teachers and was sold to personnel departments in many large school districts. The second was sold to more than a hundred
teacher education institutions to evaluate college students who aspired to teach. The third, and most influential, project was sponsored by the Carnegie Foundation to assess the quality of secondary and higher education in Pennsylvania. Led by William Learned and Ben Wood, this effort contributed to a series of college and graduate testing initiatives, including the Graduate Record Examination.

Learned and Wood’s publicized their findings nationally and laid a foundation for dialogue about the intellectual and academic abilities of prospective teachers, even those who were graduating from Pennsylvania’s strongest institutions of higher education. The average score of the teachers, they asserted, was below that of everyone else who took the examinations except those seeking careers in business, art, agriculture, and the secretarial sciences (Learned & Wood, 1938; Sedlak & Schlossman, 1986; Warren, 1985).

Even worse, the prospective teachers in professional courses of study did poorly when compared with the high-school students who were tested. Learned and Wood’s comparisons led them to stinging conclusions about the “limited mental ability of the individuals who are specially prepared for teaching positions,” whom they identified as “narrower people” with “uninformed and incompetent minds” and skills, appropriate for elementary teaching perhaps, but unsuited for more-responsible positions in high schools (Learned & Wood, 1938, pp. 351–353). Commentators generally avoided calling attention to the painful comparisons, although Lewis Terman, a veteran of twentieth-century testing campaigns, classified some prospective teachers as “congenital ninth graders” (Terman, 1939, p. 112).

Ben Wood, one of the senior researchers in the Carnegie project, was appointed as director of the Cooperative Testing Service of the American Council on Education in 1930. With extended support from the Rockefeller-sponsored General Education Board, the service was charged with preparing, publishing, and distributing subject-matter examinations (McConn, 1931). In addition to cooperating with university testing bureaus across the nation, the service donated examinations to a variety of organizations, including the Carnegie project. Increasingly engaged in test construction and administration, school leaders in Providence, Rhode Island, requested a special edition of the service’s examinations in 1932 “for use as one phase of their teacher selection procedure” (A. Wilson, 1985, p. 11). Other districts learned of the service’s generosity, and within a few years, districts in Philadelphia, Pittsburgh, and Cleveland were being supplied with tests. Because the General Education Board funding was to expire in 1940, the service announced that it could no longer continue to supply districts with the tests. Disturbed by this threat, superintendents from several large districts met with the American Council on Education in 1939 and formed a National Committee on Teacher Examinations to ensure a continuous supply of tests to enable their personnel departments to identify and hire the best teachers.

Soon thereafter, the entrepreneurial Wood announced that his “teacher examination service” would help employers grapple with inconsistent certification standards. Trying to convince teacher educators that his service was not encouraging superintendents to circumvent the professional credentialing enterprise, Wood stressed that the examination was just “one phase” of the selection, hiring, and promotion process. But his tendency to condemn the “horde of semi-literate who flaunt their diplomas before the credulous eyes of employer superintendents,” or his observation that “education classes are as much if not more amply populated with morons than other departments,” did little to ease the skepticism teacher educators maintained about the service (Wood, 1936, p. 381; Wood & Beers, 1936, p. 498). Upon hearing about the new testing venture, for example, the president of Shippensburg (Pennsylvania) State Teachers College challenged Wood in the pages of the Harvard Educational Review. He feared that the prestige and power of
the American Council of Education could make the proposed examinations popular and influential enough to cause a great deal of inadvertent damage: “A note of warning should be sounded against a procedure which, under the guise of providing an improved teaching service to our schools, may actually destroy the gains of several decades of intelligent planning for a better teaching personnel” (Rowland, 1940, pp. 277–288). Others feared that teacher education programs would be reduced to “tutoring schools for the passing of these tests.” Pressured by his funding agency, Wood was forced to temper his enthusiasm for the tests and to do whatever he could to mend ties with the professional educators he had embarrassed and offended for several years. To an audience at the conference of the American Association of Teachers Colleges, he admitted that “objective examinations do not and cannot measure the total subtle complex which we call teaching ability” (quoted in A. Wilson, 1985, p. 15).

It took more than a year of focused effort to complete the battery of instruments that would comprise the first National Teacher Examination. The final incarnation consisted of a group of multiple-choice tests that totaled twelve hours in length. The set included an eight-hour common examination on reasoning, comprehension, expression, contemporary affairs, social problems, subject-matter fields, and a series of segments on professional issues like education and social policy, child development, and methods (Ryans, 1940, pp. 275ff.; A. Wilson, 1985, pp. 18–23; Wood & Beers, 1936). Most of the examination assessed prospective teachers’ knowledge of basic college-course content and familiarity with current affairs, many questions being on military matters and New Deal politics. The “professional studies” component of the examination, totaling two hours out of twelve, was intentionally kept relatively small, Wood claimed, to avoid giving the impression that the testing service intended to exert “any undesirable influence on the teacher training curriculum.” Professional knowledge items, consequently, were designed to assess familiarity with indisputable fundamentals: the awareness that John Dewey was the “chief contemporary exponent of the experimental method in philosophy,” for example; or the recognition of various titles of “progressive” publications; or the knowledge that the best way to control adolescents was to exploit their obsession with “social approval.” The superficial, definitive nature of such questions probably did little to calm the fears of the community of teacher educators. Once the examinations began to be administered during the 1940s, members of the teaching profession joined teacher educators in condemning the use of the National Teacher Examination as a measure of “good teaching” (A. Wilson, 1985, 1986a, p. 6).

From the moment of its inception, the “professional knowledge” component of the NTE faced criticism. Some complained that the professional segment was weighted far more heavily than its actual share of the exam warranted (A. Wilson, 1985). Others maintained that the questions were essential political, serving primarily as a form of loyalty oath to the tenets of progressivism. One reporter, who took the NTE and then interviewed other examinees during that first year of administration, observed that in the professional test, “one seemed to sense rather immediately that certain answers were expected.”

Many questions in this area seemed to have reference to attitudes rather than to information,” [he continued]. From the wording of the questions one would probably conclude that the answer desired that which would be given by one who stood somewhat to the left educationally, by one who would be classified as a liberal or a progressive.

He also found, as other reviewers of mass examinations had since World War I, that there was an “urban tonality” about many questions. Readers of New York City newspapers, he concluded, had a definite advantage. An “observant Easterner has a better chance to make a good score than an observant Midwesterner or Southerner.” This
“metropolitan cultural” bias was ultimately undemocratic he wrote. And he found the multiple-choice—forced single choice—format to be particularly ill suited for questions he considered “dogmatic.” The new technology of the pencil lead reading scoring machines reinforced his frustration: answers that he wanted to explain or develop—out of a defiant attitude about their content—were simply marked right or wrong (Winetrout, 1941, pp. 480–481).

Just as the surplus of the 1930s spawned the National Teacher Examination, the abrupt conversion of the labor market to one of dramatic shortage—occasioned by World War II—derailed the movement to expand the NTE. Its initial role as a supplementary sorting instrument to help screen certified teachers for districts encumbered by too many applicants was undermined as the War drew off so many prospective teachers that even the largest districts had little use for such a device. In fact, backers of the NTE quickly reduced expenses by cutting the scope and scale of the examination sharply, from twelve hours to three and stopped preparing new questions for a number of years.

Ever the opportunist, Ben Wood took advantage of the South’s determination to sustain racially based dual salary schedules that the U.S. Supreme Court invalidated in 1940 to keep the National Teacher Examination afloat. Immediately after the Court ruled, southern states began to consider new proposals for hiring and paying teachers. South Carolina, for example, established a new test-based certification system for both prospective and continuing teachers: it would bestow “graded” credentials (with different salaries attached) on the basis of performance on the “objective” NTE. Wood rethought the marketing strategy for his test, and, although he was privately concerned about “getting mixed up in the racial problem,” he quickly saw the advantages of casting the NTE as a mechanism that would assist southern states in maintaining separate educational systems and opportunities while also meeting the objectivity challenges that the Court imposed (Baker, 1995, pp. 55ff.). He organized a series of conferences across the South to promote a scheme that would not award the same certificates to “persons of very unequal ability.” He reassured his white audiences that African American teachers tended to score in the bottom quintile, and was pleased that superintendents from across the region believed that the NTE could be of “great assistance in working out a constructive solution to the problems brought to focus by the [Court’s] opposition to dual salary schedules in the] Norfolk decision” (Baker, 1995, p. 55).9

Wood’s case was persuasive: within the next year, district after district, state after state, “began using test scores to legitimize so-called merit systems that reproduced salary differentials,” according to John Baker’s close analysis of the situation (Baker, 1995, p. 56). In Florida, for example, the use of the test led to patterns like the following: in Tampa, 84 percent of the white teachers, but only 6 percent of the African American teachers ranked on the highest rung of the pay scale; 80 percent of the blacks and only one percent of the whites occupied the lowest. In Palm Beach, 60 percent of the African American teachers were in the lowest salary group; no whites were in that group, and no blacks were at the highest salary rung (Baker, 1995, pp. 57–58). The courts endorsed this system because of its presumed “objectivity and validity.” The NAACP and Thurgood Marshall were able to make no headway in blocking the new certification and merit-based schedules. Wood was most successful in South Carolina, where he “prepared the way” for the state to rely on the NTE in constructing its salary schedule (quoted in Baker, 1995, p. 59). A special committee that was convened to assess Wood’s role in shaping state policy concluded that he helped to convince officials that since the tests could be scored “objectively and impartially,” they would “not be subject to the accusation that they were used for the purpose of discrimination” (quoted in Baker, 1995, p. 60). Despite numerous claims that the NTE lacked validity—one investigator in South Carolina
observed that that there was little assurance “that there is any close relationship between what a person can do on this examination and his excellence in teaching”—appeals to the scientific objectivity of the exam coupled with projected racial disparities in performance led the legislature to approve the NTE based salary policy in 1945 (quoted in Baker, 1995, p. 61).

Although Ben Wood became “rather frightened about further publicizing our [NTE’s] relationship in this matter” of test-based differentiated salary schedules, his successors pressed to expand the exam’s role in hiring and reward policies across the nation, particularly in the South. Ironically, after the NAACP’s victories during the 1950s, the Brown decision in particular led to “greater use of the exams in the South” (quoted in Baker, 1995, pp. 63–64). Within just a few years, teacher and administrator testing was mandatory throughout the southern states, and was required in every major city. In addition to expanding differential salary schedules, the NTE was increasingly used, in the sobering analysis of Scott Baker, “to demote and dismiss thousands of African American teachers in desegregated school systems” (Baker, 1995, p. 64).

Nationally during this time, the continuing teacher shortage—instigated by the war and aggravated sharply by the arrival of the first wave of the Baby Boom generation into the elementary schools after 1952—influenced strategies for recruiting, licensing, and hiring teachers. Following a brief flirtation with “emergency” certificates, bestowed during the war on individuals otherwise unable to secure teaching positions through established licensure routes, states and districts tried to attract teachers with higher salaries, publicly supported financial aid and loan forgiveness programs, and deferments from the military draft. Paralleling the shortage of the 1920s, certification standards were actually raised during the period after World War II. By this time, almost all state policies were based on professional educational credentials, so attention focused on the scale, scope, and substance of the academic and professional preparation available to, and required of, prospective teachers. Between 1940 and 1967 the minimal professional component expanded very slightly, to roughly 28 semester hours at the elementary level and 18 at the secondary level. Most institutions offered programs that required more than these minimums, however: a survey of accredited institutions in 1958 revealed that elementary programs more typically required 36 hours, and secondary programs 24 (Stinnett, 1969, pp. 418–420; Armstrong, 1951; Woellner, 1946, 1949, 1952). Extended clinical experiences (as student teachers) became customary.

As these standards were raised, an intense struggle ensued during the 1950s and 1960s over teacher certification and preparation. In most respects, the struggle was ideological and rhetorical; the actual framework for licensure remained quite stable for the four decades following World War II. The hegemony of the loosely-coupled professional education enterprise—state education and certification authorities, teacher preparation institutions, K-12 teacher organizations, was increasingly challenged by another loose collection of intellectual, political, and professional interests, led for the most part by discipline-based academic faculty in colleges and universities.

Like the progressive factions that shaped policy during the early twentieth century, these two groups were driven by similar motivations: to impose their vision of educational purpose and teaching methodology on the nation’s schools, and to advance their respective career interests. Unlike their progressive predecessors, however, the two groups in the 1950s and 1960s differed radically in their proposals for preparing, licensing, and recruiting K-12 teachers. The “educational trust,” or “educationists,” as the first group became known, continued their century long campaign for expanding and refining professional credentials based on increased levels of preparation, and for deepening the influence of practitioners in the training and hiring processes. The academic disciplinar-
ians criticized the value of professional education, and opposed all of the burdensome state policies that based certification on extended professional preparation; they believed that a strong liberal arts education at a demanding four-year institution of higher learning was sufficient preparation to teach K-12 school subjects.\textsuperscript{10}

This was the most vicious manifestation of what was becoming a perennial dispute between those who were committed to a broad, socially ambitious agenda for the schools, and those who advocated a narrower purpose, focused principally on ensuring the acquisition of school knowledge in the core academic subjects. Certainly since the 1920s, under the vision expressed most popularly in the \textit{Cardinal Principles of Secondary Education} (1918) and subsequently through the policy and implementation statements associated with the “life adjustment movement” of the late 1930s and 1940s, the first group had grown more dominant. At least the American curriculum had adapted to this vision of serving the masses of children and adolescents that were attending the public schools. Other historians have thoroughly reconstructed this pronounced shift in the stated goals of schooling, away from concern with intellectual development and mastery of subject matter to concern for social and emotional development and to the adoption of “functional” objectives related to areas such as vocation, health, and family life (Ravitch, 1983, p. 55). So this chapter will address the movement away from elite, classical learning towards universal, inclusive (if highly differentiated) “socially relevant” learning only briefly, as assumptions about the education of children are intimately related to assumptions about the preparation of their teachers.\textsuperscript{11}

The curriculum expanded aggressively to serve the presumed interests and needs of millions of working class and immigrant children who had traditionally abandoned systematic schooling during the elementary years. Claiming that it was undemocratic to force such children to endure the aggressive classical curriculum that had appeared to serve the needs of the handful of adolescents who would attend college or enter privileged economic and social positions, the reformers added an array of vocational, practical, and personal development experiences to the curriculum. And they fragmented the traditional disciplines, both to accommodate the students they thought were incapable of rigorous academic work, but also to infuse those subjects with new relevance and purpose. When they could afford it, many districts added social and health services. As they became less exclusive, many schools became far more internally stratified and differentiated. These innovations were essential, in the words of an influential report to the American Youth Commission of the American Council on Education, to meet the needs “of children of mediocre or inferior ability who lack interest in abstract and academic materials.” Stimulating the final phase of the life adjustment movement, this study, released in 1937, posed the challenge of modern curriculum design by arguing that the course of study need not include subjects, or aspects of them, merely because they have made significant contributions to civilization. It is impractical to confuse, as is so commonly done, such values with the utility of subject matter for the education of the masses of young people today, however essential it may be that a small number of experts be well trained in these matters (quoted in Ravitch, 1983, pp. 60–61). The pressure towards life adjustment accelerated over the next few years. The prestigious Educational Policies Commission released its powerful argument to have schools meet “the imperative needs of youth” in 1944, called \textit{Education for All American Youth}. Challenging the historical classical defense of traditional disciplines, the Commission claimed that in the future there should be “no aristocracy of ‘subjects’,” and that “mathematics and mechanics, art and agriculture, history and homemaking are all peers.” Diane Ravitch has reconstructed this intensifying campaign through the late 1940s, and its impact on American schools, at least on their curricula (Ravitch, 1983, especially pp. 62–63).
It is not surprising that this expression of ambitious social expansionism through schooling provoked a variety of critics. Building on the narrower academic disciplinary objectives of William C. Bagley and the “Essentialists” of the 1930s, the critics coalesced during the early 1950s, and engaged the professional educational establishment in “the great debate,” as it became known. Despite their radically varied motives and inspirations, the “anti-progressives” rallied around their common enemy—the life adjustment movement—which was a “bloated target,” in Ravitch’s memorable image (Ravitch, 1983, p. 70).

The more thoughtful critics shared Mortimer Smith’s outrage regarding the progressive assumption of equality of knowledge. This former school board member rebelled at the notion that “no subject is intrinsically of any more value than any other subject . . . training in mechanical skills is put on a par with the development of mind and imagination . . . hairdressing and embalming are just as important, if not a little more so, than history and philosophy” (Smith, 1949, pp. 21–24, 42, 59–60, 92–93).

Critics rather quickly began to shift the blame towards the teacher education community, which they held accountable for the disturbing anti-intellectual hostility to the classical curricula and traditional teacher-directed methods. A liberal arts faculty member at the University of Illinois viciously attacked professors of education, who he argued converted teachers into “wet nurses, instructors in sex education, medical advisors, consultants to the lovelorn, umpires in the battle of the vertical versus the horizontal stroke in tooth-brushing, and professors of motor-vehicle operation.” He thoroughly condemned faculty in education schools, from their enthusiasm for “socially relevant” curricula, to their “flatulent prose” masquerading as scholarship (H. Fuller, 1951, p. 34).

One of his colleagues at Illinois at the time, history professor Arthur E. Bestor, Jr., moved quickly to address the essential problem: the usurpation of authority by the pedagogical faculty for teacher education in the university setting. In an address to the University of Wisconsin in early 1953, which would be later expanded in his comprehensive assault on prevailing educational practice and philosophy, Educational Wastelands, Bestor blasted professors of education who “represent themselves” to the public as the only legitimate segment of the university to speak about the broader aims and purposes of schooling. And this faculty group “contrived to put across the completely unfounded notion that the proper way to prepare for a career in teaching” was to take courses in “education, so-called, that is to say, in pedagogy” (Bestor, 1953, p. 82). He was not opposed to pedagogy as a research field, and claimed that as a history teacher he drew successfully on important scholarship of learning, textbook effectiveness, and adapting instruction to students of differing intellectual capacity. But, he continued, “the effective teacher of history requires many qualities of mind and personality, many varieties of knowledge, and many intellectual skills, among which pedagogy is only one.” His main point was that “obviously every teacher must have some knowledge and skill in pedagogy just as a doctor must have some adeptness as what we call ‘bedside manner.’ ” But such study is not what should be central in medical education, or in teacher education. “What counts in a doctor is his knowledge of medicine, and what counts in a teacher is his knowledge of the subject he is teaching. To expect to produce a good teacher by training him mainly in pedagogy is as foolish as to expect to produce a good doctor by loading him down with courses in bedside manner.” If we operated medical schools as we did colleges of education, he stated, “we would all be done to death by cheery and plausible doctors who would know all about how to practice medicine but who would not be quite sure whether human beings have gizzards or not.” Preparing teachers was one of the university’s most critical functions, and it would never be done well until it was done by “the university as a whole.” Delegating it to the department or college of education was a “principal
cause of the alarming anti-intellectualism of so much public education today” (Bestor, 1953, p. 82).

Bestor blamed liberal arts and sciences faculty for allowing this troubling condition to develop. They had failed to be vigilant about public education, about the needs of teachers. Because they failed, the arrogant educationists had “rushed in to fill the vacuum.” The academic disciplinarians must recapture authority over the structure and substance of the undergraduate curriculum, he said. Minimum study in teaching methods could be completed in an elective course or two. But, he warned, “under no circumstance should the department of pedagogy be permitted to exercise any sort of control over the undergraduate programs of prospective teachers” (Bestor, 1953, p. 83). Even at the graduate level, virtually all coursework needed to be in the academic disciplines, not in pedagogical fields. And research on pedagogy, learning, and administration should be shared among the social sciences. He then turned to the legal framework—state-imposed certification requirements—those stood as a barrier to his “rational program of teacher training.” Sensitive to the institutional and personal economics of university-based teacher education, he argued that “these requirements are, in reality, special interest legislation—a kind of protective tariff—enacted for the most part at the behest of professional educationists.” He wanted to replace these codes with law that would “protect the schools against incompetent teachers rather than the professors of pedagogy against losses in enrollment” (Bestor, 1953, p. 85). Statutes that required minimum credits in professional education needed to be stripped. “Dethroning these requirements from their peculiarly privileged position” would help to open the teaching market to a “large and brilliant group of liberal arts graduates who are at present excluded from public-school employment by unjustifiably arbitrary pedagogical requirements.” Finally, this realignment of certification and preparation would “bring to an end the aimless accumulation by experienced teachers of credits in pedagogical courses,” and would do more than anything to “restore the repute” of public schools more than any other single reform. This change would appeal to those with genuine intellectual interest and capacity, who would not be “repelled at the outset by being asked to lay aside their intellectual interests and fritter away their time in the courses of pedagogues” (Bestor, 1953, p. 87). Such a teaching force would also be ready and able to resist the anti-intellectualism of the new wave of vacuous progressivism that was about to greet the baby boomers as they entered their first classrooms.

This argument of Bestor and his allies in the liberal arts departments reflected both a countervailing view of educational purpose, and a keen sense of their own political economics and career interests, a perspective that echoed the opposition of the liberal arts colleges and classical academies to the expansion of normal schools after the Civil War. Over the twentieth century, the expansion of professional studies for prospective teachers rose steadily, tripling from about 10 or 11 credits in the early 1900s, to well over 30 by 1950. The total size of the course of study leading to the bachelor’s degree did not increase that much, so in many ways, in the zero-sum game of the undergraduate curriculum, the expansion of professional coursework displaced classes in the liberal arts and sciences disciplines (in general education, academic majors, and electives). As teacher education became an increasingly large segment of university work, the rise in influence of the faculties of education, and their influence over public discourse and policy, reduced the role of academic disciplinarians. Their aggressiveness in the 1950s represented in part a renewed quest for public legitimacy and institutional authority, just as had the quest of the professional educational community during the prior generation. There is no doubt that serious differences in philosophical and political visions divided the groups, and shaped the substance of their claims and campaigns. But private ambition and collective interests intensified the hostilities.
The rivalry deepened in the later 1950s and early 1960s, accelerated in part by the national response to the launch of Sputnik in 1957 and the concentrated campaign to restore disciplinary hegemony over the schools’ academic curricula, particularly the effort to energize math and science teaching and learning. University faculty in the arts and sciences largely commandeered the public and foundation investments in the curricular and instructional reform movement—and the underlying research—of those years. This was another expression of the competition for resources and authority between the teacher education community and its university-based critics (Church & Sedlak, 1976).

The assault’s intensity peaked in 1963, with the near simultaneous publication of two indictments of the state of K-12 schooling in general and of teacher education in particular, one sympathetic, the other scathing. James B. Conant, former Harvard president and author of the relatively liberal and supportive endorsement of the American high school, wrote *The Education of American Teachers*. For the times, this book was also surprisingly generous toward the teacher education and certification enterprises. He appreciated the difficult market conditions that shaped the constraints on schools of education, and he challenged the academic disciplinarians to care about improving the way that their subjects could be more effectively taught. Conant did anger teacher educators, however, by expecting them to share responsibility for preparing teachers with both their colleagues in the academic disciplines and practicing classroom instructors; his enthusiasm for the student-teaching apprenticeship experience also implicitly denigrated their higher education-based professional courses (Conant, 1963; Judge et al., 1994; Stinnett, 1967).

Despite his claim to have studied teacher education “dispassionately” and “undogmatically,” James D. Koerner, the author of the second book released in 1963, infuriated virtually everyone associated with preparing teachers, administrators, and other specialists for the educational system. His blunt and humiliating study, called *The Miseducation of American Teachers*, condemned teacher and administrator educators, students planning careers in education, and state licensing staff alike. Here are his most notorious complaints (Koerner, 1963; Labaree, 2004).

3 Education as an academic discipline has poor credentials . . . [I]t has not yet developed a corpus of knowledge and technique of sufficient scope and power to warrant the field’s being given full academic status. That it has been given this status in most of our colleges—or, more accurately, that it has achieved this status through the abdication of responsibility by the academic departments—does not make Education a genuine discipline; it only makes possible the building of more academic empires on sandy foundations.  

5 It is an indecorous thing to say and obviously offensive to most educationists, but it is the truth and it should be said: the inferior intellectual quality of the education faculty is the fundamental limitation of the field, and will remain so . . . [T]here is still a strong strain of anti-intellectualism that runs through the typical Education staff, despite their increasingly frequent apostrophes to academic quality.

6 Likewise, the academic caliber of students in Education remains a problem, as it always has. Fortunately, there is some progress here, more so, ironically enough, than with faculty. Many schools in the last few years have succeeded in raising the level of admission requirements to the teacher-training programs, which has been possible chiefly because the requirements were so low to begin with.  

7 Course work in Education deserves its ill-repute. It is most often puerile, repetitious, dull, and ambiguous—incontestably. Two factors make it this way: the limitations of the instructor, and the limitations of subject-matter that has been
remorselessly fragmented, sub-divided, and inflated, and that in many cases was not adequate in its uninflated state . . . [T]he intellectual impoverishment of the course work remains a major characteristic of the field.

8 The quantity of Education courses in the typical teacher-training program also deserves the harsh things that have always been said about it. According to my survey of transcripts credit, secondary teachers of academic subjects take an average of 27 semester hours in Education. This is close to a year’s work in most colleges and is clearly excessive. Elementary teachers take an average of 49 semester hours in Education. This is about 40 percent of their undergraduate careers, and is, I submit, wholly indefensible. These averages go even higher among teachers colleges and many university schools of Education; they are brought down nationally by the liberal arts colleges. The figures speak for themselves: a severe curtailment in the quantity of these courses is needed.

11 The academic component of a teacher’s education, which remains, after all, the primary one, is also in need of attention. Course work in academic areas is sometimes not much stronger than in Education, a fact that academicians ought to face with candor . . . Although academic teachers have certain advantages over their Education colleagues in training and in the natural viability of their material, and although they are certainly more effective in their students’ eyes than are Education professors, all indications are that course work in the liberal arts areas could immeasurably better than it is . . . If high school teachers are often incompetent, a large share of the responsibility must be accepted by the academic departments.

(Koerner, 1963, pp. 17–19)

Like many other critics of the educationist community, Koerner held a comparatively narrow and academic view of the purpose of education. “We have no choice but to assume Western civilization is good,” he began. “Our civilization is the product of a long and painful process of taming, training, and refining the human animal, a process made possible by two characteristics that distinguish man from all other creatures: intelligence and compassion.” Education could do its job of continuing to raise humankind out of savagery by “training the intellect of each new generation vigorously and systematically in those subjects that are the most fruitful for man’s continuing development” (Koerner, 1963, pp. 6–7). Like others, he railed against the anti-intellectualism that he believed pervaded the most recent expression of progressive ideology. But, interestingly, Koerner differentiated sharply between educational purpose and the pedagogies that were most likely to achieve those ends. Although he opposed vocational, life adjustment, and other practical or utilitarian functions for education, he agreed with pedagogical romantics like Rousseau and even John Dewey. “How this kind of basic education can best be carried out in a classroom is another question,” he said. “Let us by all means adopt those methods of progressivism that involve the student as actively as possible in the learning process. And let us by all means champion those views . . . that seek to reduce the cruelties or the senseless coercions of the classroom that, it is said, used to constitute education.” And, unlike many of his contemporaries, he believed that the “great majority of people” could respond to the opportunities of a “liberal education when it is conducted well” (Koerner, 1963, pp. 9–10).

Although the academic disciplinarians played a compelling leadership role in the campaign, there were other constituencies, whose interests and aspirations were rooted in recent social and demographic changes, who tried to challenge the educational trust. In particular, the ambitious professional and middle classes, residentially concentrated in
the flourishing suburbs, had grown uneasy about the erosion of academic focus in the schools. Many of them owed their career achievements, status, and modest wealth to their educational attainments and credentials. Many had graduated college, and had even earned professional and master’s degrees, some with the aid of the G.I. Bill. They were committed to the installation of the emerging American meritocratic state, which recognized and rewarded educational accomplishments. They wanted to protect their children’s futures by investing in advanced educational credentials, which would open access to privileged occupations. Thus, they resonated with the anti-life adjustment commentary and resisted the political movement to convert the high schools into terminal educational institutions dedicated to serving the social and vocational needs of the non-college bound masses. They were attracted to the arguments of Bestor and other academic faculty who endorsed the narrower, more elite college preparatory purpose for the K-12 system (Church & Sedlak, 1976, p. 422).

While this line of criticism was building, various constituencies of the unraveling educational trust were pressing ahead with distinct agendas of their own. The largest group, the classroom teachers, began mobilizing during the 1940s, just as World War II ended. David Angus has reconstructed the aggressive efforts of teachers, whose voices had eroded under the domination of their professional education partners—the teacher educators and state educational authorities. At the end of the war, the teaching corps was “grossly overworked, underpaid, and demoralized,” Angus observed, and felt that after a half-century of educational investment and expansion of power in the educational enterprise, “the benefits had not trickled down to them” (2001, p. 19; see other “trickle down” imagery in E. Fuller, 1952, pp. 26–7). They turned quickly to the National Education Association, which had been gradually turning away from collegiate leadership, to create the National Commission on Teacher Education and Professional Standards (NCTEPS, TEPS for short) in 1946. Rooted in the NEA’s department of classroom teachers, TEPS was the first initiative intended to fashion an “independent voice” for teachers that would begin to challenge the dominance of university-based professional school faculty “over teacher education and certification” (Angus, 2001, p. 20). Seeking to play a larger role in controlling entry to teaching, a critical ambition of all occupations undergoing professionalization, TEPS launched what has become known as the “professional standards movement” in education. The New Horizons Task Force, for example, was dedicated to achieving “a self-directing profession of teaching, which is capable of assuming responsibility for the competence of its members” (Kinney, 1964, p. 92; Topp, 1957; Benham, 1979).

For the next few years, TEPS organized conferences on a variety of certification and preparation issues. Under the banner of “democratizing” the discussion of professional licensing, the TEPS strategy was to expand the role of practitioners over state policymaking and to influence the content of teacher education. They largely succeeded in their effort to centralize all certification authority in the state departments, which were to be advised by advisory councils, whose membership was to include TEPS officers and classroom teachers, a maneuver to circumscribe the power traditionally held by education deans (Angus, 2001, p. 20). This led to a critical drive to overturn traditional state practices of allowing teacher education programs essentially to design themselves, which resulted in idiosyncratic approaches that made certification reciprocity very difficult and costly to teachers who wanted to pursue market opportunities across state lines (see E. Fuller, 1952, p. 27). Classroom teachers joined critics of education schools in condemning the low standards of admission and weaknesses in preparation. One of the TEPS leaders observed in 1950 that the
teacher education system of the United States, with the exception of a very few states, is a hodgepodge of programs which are in the main a travesty upon professional education . . . We even provide a better-planned and better-financed system of professional education for those who raise pigs than we do for those who teach children. (quoted in Angus, 2001, p. 21)

Neither Arthur Bestor nor James Koerner could have phrased it more imaginatively. Several organizations cooperated to promote an alternative to the state-by-state “approved program” approach. TEPS, the National Association of State Directors of Teacher Education and Certification (NASDTEC), and the recently formed American Association of Colleges for Teacher Education (AACTE) collaborated to establish in 1952 a national external accreditation body to develop and enforce national standards on the 1,200 institutions then preparing teachers. The resulting organization, the National Council for the Accreditation of Teacher Education (NCATE), was charged with raising preparation standards across the nation and to build “general public opinion in support of professional status for education” (National Council for Accreditation of Teacher Education, 1951; E. Fuller, 1952, p. 28; Russell, 1952; Tuttle, 1953; Lieberman, 1960, pp. 191–201). Modeled on councils operating in two dozen occupations at the time, NCATE was to operate initially under a shared leadership of classroom teachers, professional education faculty, and state certification officials. During the period of the “great debate,” NCATE leadership respectfully addressed some of the concerns raised by Bestor and other academic disciplinarians. Aware of the critique that was rooted in the competition for space in the zero-sum higher education curriculum, for example, NCATE’s director, W. Earl Armstrong laid out a model for a balanced “teacher education curriculum” (Armstrong, 1957). Speaking from a draft “thought piece” from the Council, in 1957 he argued that the ideal preparation would include a broad immersion in general-liberal studies, a subject matter major, a limited, coherent, and practice-based set of professional coursework. He noted emphatically how difficult this was to achieve in the typical four-year undergraduate program, and stated that “the period is rapidly approaching when a minimum of five years of college preparation will be regarded as essential for all fully qualified elementary and secondary school teachers” (Armstrong, 1957, p. 241, emphasis in original). As society became more complex and knowledge expanded exponentially, as the social demands on education multiplied, and as the general public became more educated—and their confidence in the teachers in their communities depended upon equivalent credentials, he elaborated, “the need for more than four years to accomplish the total program becomes more apparent” (p. 241). Armstrong wanted to expand broad liberal arts learning by shifting some disciplinary specialization and professional education to the fifth year, which he also argued should be completed as an induction experience once the teacher was employed. He did not specify the relative scale of these essential components of the program, but said that the entire university community—liberal arts and professional education faculty alike—should come together to discuss the goals and size of the proportions (Armstrong, 1957, p. 241; see also Selden, 1960).

Armstrong’s tentative proposal stimulated discussion, but little action. One of the most thorough responses was offered by educational philosopher Harry Broudy of the University of Illinois, who claimed that the NCATE proposal basically conceived of school teaching as “a genteel, white-collar craft” because it appeared to debase genuine, theory-driven professional knowledge, and substituted highly specialized but limited skill development in field settings. What sorts of “intellectual, economic, and social status” can mastery of such limited craft training command, he asked? If brevity and a low risk of
failure is all there is to this corrupt “professional” education, he could “foresee the logical end of this trend:”

The claim that a liberal arts degree plus some student teaching is enough; the liberal arts degree with apprenticeship in some school system at somewhat reduced salary will be suggested; then it may occur to someone that perhaps a high school diploma and apprenticeship might do... If teaching is merely a craft, then sooner or later the apprenticeship pattern of training will displace all others, because we learn a craft by doing it; the craft of teaching is best learned by teaching.

(Broudy, 1959, p. 109)

Broudy concluded by noting that if the Council’s proposal could lead to productive dialogue and the improvement and national upgrading of teacher education, “it will have contributed to the salvation of professional education.” But if the proposal was taken as the solution, it would be “one step toward suicide—a lingering, gradual suicide but ultimately fatal, nevertheless” (Broudy, 1959, p. 112; see rejoinder by Bowers, 1959, pp. 112–116).

Possibly because of perspectives like those suggested in the Council’s 1957 proposal, NCATE underwent restructuring several times over the next three decades, each time causing the classroom teachers to lose influence, and teacher educators to achieve a voting majority (Angus, 2001, p. 21; Kinney, 1964, pp. 92ff.; Armstrong, 1960, p. 9). And, as Angus observed, teacher militancy and unionism, both hallmarks of anti-professionalism during the 1960s, left practitioners in the NEA and AFT with even less voice over certification and teacher education.

NCATE accredited comparatively few of the nation’s teacher education programs during the 1960s and 1970s, although it did engage many of the largest institutions. NCATE came to be seen as an expensive process that had not been able to fulfill its promise of substituting for state approval and ensuring national licensure reciprocity. Further complaints from many communities about the ability of the most notoriously weak programs either to avoid accreditation altogether or to slip through vulnerable enforcement procedures led the NEA and AACTE—both troubled by NCATE’s deteriorating stature and influence—to institute new leadership and to fund a major three-year study of the organization in 1977. Led by Christopher Wheeler of Michigan State University’s Institute for Research on Teaching, the analysis thoroughly probed all of the activities that occurred during the accreditation process (Wheeler, 2005; Wheeler, 1980; Watkins, 1980). Wheeler found that NCATE accreditation was actually improving some of the worst programs it examined; at least when the process was professional and taken seriously these institutions benefited from the review. But, more often, a variety of pressures led the NCATE visitation teams to conduct relatively superficial investigations. The composition and analytical depth of the teams was too easily manipulated and compromised, he found, because the institutions could veto team members, and often did so when a potential visitor had a reputation as too rigorous or had found too many problems with other programs (Wheeler, 1980, p. 57). The host institution’s attitude about external accreditation also frustrated NCATE leaders and team members. “We saw NCATE as a problem to get over with in the least costly way,” one program leader told Wheeler. He spoke candidly about the review:

The faculty in our College of Education was hostile to NCATE, so we decided to keep the process as quiet as possible. Only the department chairperson and I knew it was coming up. I wrote the entire Institutional Report to cover over our problems.
Then we tried to get faculty members who might cause trouble out of town during the visit and we primed the others. We deliberately pushed for a small NCATE team on the assumption they would not be able to penetrate deeply because they would run out of time.

(Wheeler, 1980, p. 57)

This gamesmanship strategy worked: NCATE accredited all of his programs. Combined with vague and weak standards, the visiting teams were too often forced to conduct a shallow review, and were left with few alternatives to the prevailing practice of determining whether there was a “presence or absence” of a standard, or a problem: they could rarely comment on whether the teacher education program was doing well. Wheeler found this minimum standards approach to be a significant impediment to influencing moderately successful programs in positive directions (Wheeler, 2005; Tom, 1980a; Gubser, 1980; Wisniewski, 1981; Tom, 1981; Tom, 1980b). Provoked by this stinging critique about its processes, and by other substantial questions about its standards, NCATE devoted a number of years to revising its practices. Internally, NCATE leadership was challenged, and both the NEA and AACTE called for new leadership and directions. Art Wise, of the Rand Corporation, was brought in to shepherd the reforms, particularly to move the accreditation process towards revitalized standards and outcomes-based performance assessments.

Despite several decades of controversy and activity, the ways that teachers became licensed and hired had changed only modestly by the early 1960s. Over the prior 30 years, states increasingly relied on professional education credentials to certify new teachers. Even as the “Great Debate” was winding down, teacher educators remained solidly in control of most of the details of professional preparation. State officials did indeed define the basic requirements, but higher education institutions retained considerable autonomy in enacting the public guidelines. National accreditation spurred some efforts towards consistency across states and regions, and helped to elevate some of the weakest preparation programs. Resurrected through the National Teacher Exam, testing had begun to stagger out of the embarrassing awkwardness of southern racial politics, but was not yet meaningfully influential in models of initial certification. Certainly more constituencies had begun exercising their voices, but they were not yet affecting the policy landscape in significant fashion.

The immense shift in the political landscape that occurred during the 1960s, as the educational enterprise was drafted into the War on Poverty, delayed the convergence of ideologies and self-interests that would eventually reshape certification policy during the 1980s. President Lyndon Johnson’s ambitious domestic agenda in 1964 and 1965 revitalized the languishing vision for expanding the social function of education, which had contracted during the 1950s. The aggressive focus on disadvantaged and non-college bound students derailed temporarily the so-called “elitist” initiatives that had received the bulk of publicity and investment for ten years. Members of the core educational communities who were committed to studying the sources and consequences of school failure, differential access to valuable knowledge, the relationship between educational achievement and adult mobility and success, and who were engaged in constructing compensatory programs, or curricula that were sensitive to class, race, and gender, were once again provided the opportunity to shape discussion and policy debates, and to have their ideas and projects privileged in competition for public and private funding. Pedagogical romanticism flourished during the late 1960s and 1970s, as schools experimented with new organizational forms like the “open classroom,” or more child-centered instructional methods, such as the use of manipulatives in mathematics classes. These
were never modal practices, and were rarely permanent, but they were popular, widely discussed in mass media, and were not as ridiculed as many expressions of the life adjustment movement had been.

After this extended period of policy consistency, coupled with growing rhetorical antagonism, the terrain of certification began to be reconfigured during the 1980s. Over the last two decades of the twentieth century, ambitious political and professional interests did not just sustain the rhetorical struggle that surfaced after World War II, but moved strategically to attempt to transform the mechanisms of preparation and licensure. This piece of the story is complicated, and this chapter concludes by just reconstructing its outline, leaving to other authors the unenviable responsibility of unraveling the subtleties and details.

The resurgence of the conservative criticism of the expanding educational vision during the 1960s, legitimized and funded aggressively for the first time by the federal government, found its initial voice in *A Nation at Risk*, released in 1983. It launched the first wave of accountability and standards reform by re-focusing attention on “excellence” and competitiveness, grounded—as was the anti-educationist perspective of the 1950s—in a comparatively narrow definition of educational purpose and achievement, associated, not surprisingly, with a rather conventional vision of pedagogy. Since the early 1980s this tension between visions of purpose and pedagogy has been integral to the policy struggles over certification. A “new Progressivism” has faced off against a “new Essentialism” in both the K-12 enterprise and in higher education. On the one side, advocates of broadening the function of education condemned the standards and excellence movement as elitist, likely to reinforce or exacerbate existing inequalities—if not intentionally, at least inadvertently as a consequence of misguided and narrow accountability initiatives. They argued that excessive and punitive testing of students often perverted teaching and learning, squandering opportunities for children to grow meaningfully through their experience in school, and contributing at best to improved scores that represented little beyond shallow test-taking gamesmanship. They advocated instead for various expressions like ambitious or “adventuresome teaching,” “conceptual learning,” or “teaching and learning for understanding.” And they supported teacher certification standards that increasingly reflected such an instructional approach. On the other side, conservatives were troubled with the expansion of purpose and content, with the broadening of the curriculum to embrace multi-cultural and practical or peripheral coursework at the expense of traditional core academic disciplinary knowledge. They were increasingly enthusiastic about direct didactical, teacher-centered instruction, believing that the spread of group work and active or project-based instruction had left classrooms far too student-centered. And they wanted to restrict teacher certification requirements essentially to collegiate subject matter preparation, denigrating virtually all university-based professional education as irrelevant, costly, frivolous, and of unproven value. In contrast to earlier conflicts, leaders from traditionally under-served communities (African American religious and neighborhood organizations, for example), who saw merit in more traditional instruction and achievement in core academic subjects as a reasonable route to improved economic opportunity, aligned themselves politically with this conservative perspective.

Ironically, much of the largely conservative animosity of the 1980s and 1990s drew heavily from the radical left’s anti-professionalism and consumerism sentiment of the late 1960s and 1970s. Scholars from a variety of disciplines (particularly sociology, political science, anthropology, and history) were joined by consumers’ rights advocates in an assault on providers of health care, education, social welfare services, insisting that professionalization in such occupations insulated practitioners from the consequences of
their work. Moreover, the early critique ran, these fields pressed for the right to control entry into the occupations, thereby enhancing professional arrogance and reducing client access and choice. More recently, conservatives and many otherwise liberal communities—again, African American civil rights leaders—resurrected this analysis and fashioned an array of market and choice solutions to weaken and derail professional ambition. In education, the anti- or competitive certification or deregulation movement embraced the earlier perspective in calling for an end to the professional cartel or monopoly over entry into teaching.

In sum, the creation and evolution of certification standards in education has been shaped by deep and enduring differences of perspective about the purpose and place of schools in our society, about what we want children to become through their experiences as students, how we think schools can best have this effect, and what sorts of people we believe we can trust with our children’s care and destinies. Certainly individual and organizational interests and ambitions have affected this evolution. Everyone in this story has had interests to advance, careers to create, enhance, and protect. Understanding and appreciating the power of those personal interests is important, but not as important as the task of beginning to disentangle these differing visions of purpose from conventional politics.

NOTES

1 This version of the treaty was recalled and captured by Benjamin Franklin, first in a letter to Peter Collison in 1753 (reprinted in Labaree, L. and Bell, 1961, p. 483); Franklin, 1784, translated the sentiment again in a pamphlet called “Remarks Concerning the Savages of North America,” in 1784 (reprinted in Smyth, 1907, pp. 98–99). This is the version quoted here. The actual treaty was translated more briefly and formally, but the sentiment was the same (Van Doren and Boyd, 1938, pp. 72–73, 76).

Several authors have begun calling attention to the ways that differing definitions of purpose have influenced the politics of teacher licensure, but no one has effectively brought this to the place of prominence it deserves; see Angus, 2001; Imig and Imig, 2006. My colleague, Patrick Halladay, and I spent a good summer discussing this matter; I appreciate his suggestions.

2 This compressed and abbreviated description of social and economic developments of the early nineteenth century is based most conveniently on Rury, 2004; Church and Sedlak, 1976; Kaestle, 1983; Reese, 2005.

3 See Sedlak, 1989; Angus, 2001; S. Wilson and Youngs, 2005; Herbst, 1989 for informative introductions to this formative period of policy creation.

4 See Church and Sedlak, 1976; Sedlak, 1989; Elsbree, 1939.

5 The most thorough and convenient examples of the origins and early history of teacher education programs are Herbst, 1989; Labaree, D., 2004 although they appeared late to influence this chapter, see comprehensive studies by Ogren, C., 2005 and Fraser, J., 2007.

6 The following few paragraphs draw heavily from Sedlak, 1989, 266–267.

7 These are widely-known distinctions among “educational progressives;” see Tyack, 1974; Church and Sedlak, 1976; Rury, 2002.

8 The most accessible and valuable historical treatments of the National Teacher Examination include A. Wilson, 1985, 1986a, 1986b; Baker, 1995; Haney, Madaus, and Kreitzer, 1987; and Sedlak, 1989.

9 The case of South Carolina has received particular attention; see A. Wilson, 1986b; Baker, 1995; Sandifer, 1984.

10 Various historians have explored this phase of the controversy; see Ravitch, 1983; Church and Sedlak, 1976; Reese, 2005; Angus and Mirel, 1999.

From traditional certification to competitive certification
A twenty-five year retrospective

INTRODUCTION

Teacher certification has become the policy tool of choice for both liberals and conservatives as they seek to reshape teaching and teacher education. Webster’s defines certification as “an official document awarded to somebody who has completed a course of study or training or passed a test or examination or conformed to a required standard.” From the question of who should issue the certificate to the form and function of preparation leading to the certificate, from the setting of program standards to the means of assessing teacher candidate proficiency, every aspect of teacher certification has been contested over the past 25 years.

During this period, we have moved from consideration of the minimal requirements for initial certification (usually consisting of academic degrees and professional education courses) to a much more complicated array of certificates gained in multiple ways (NASDTEC, 1999). Perhaps surprisingly, however, this highly complex system demonstrates little variability across states—certification requirements in New York are remarkably similar to those in Washington. Issues of interstate reciprocity, the emergence of an assessment system for beginning teachers (the original National Teacher Examination), and common accreditation standards for teacher education programs have helped to foster a national system of quality assurance in teacher policymaking.

States have moved from analyzing the transcripts of teacher candidates to embracing completers from state approved programs. States have shifted from prescribing a course of study and requiring all collegiate preparation programs to comply with those prescriptions to focusing on competency testing, ceding authority for program approval to national accreditation agencies. Today, states have added state assessments of basic skills and subject matter knowledge as prerequisites to the awarding of teacher certificates. While state policies and state governance drive the current system of licensure and certification, federal policies now influence every aspect of the certification process.

There have been remarkable developments on the national level as well. The National Board for Professional Teaching Standards was created, as were three significant reform groups in teacher education: the National Network for Educational Renewal, the Holmes Group, and Project 30. The Council of Chief State School Officers created the Interstate New Teacher Assessment and Support Consortium (INTASC) and systemic or standards-based school reform came to dominate the educational discourse. The prominence of the teacher as the most significant in-school variable for the learning of all PK-12 students became widely accepted (Haycock, 1998; Sanders & Rivers, 1996).
Political parties and business coalitions alike embraced this theme, making good teachers a national priority. Underlying these movements and efforts was the assumption that if one changed certification laws, one could change teacher quality. In this chapter, we trace the contours of the shifts in policies concerning teacher quality from 1980 to 2005. We begin with a brief overview of trends in teacher licensure and certification.

TEACHER LICENSURE AND CERTIFICATION

The granting of a license to a prospective teacher probably came into being in the late 1660s as towns and villages in New England required tests of those who sought employment as teachers. It continues today as a means to ensure that candidates “will do no harm,” that is, that they meet minimal requirements and are safe to place with young people. Certification came into existence in the mid-1800s and was influenced by the efforts of state normal schools to define a curriculum and for the state to grant a diploma or certificate for those who completed a set of state-approved conditions or requirements. County superintendents controlled access to teaching for a century (by designing and administering teacher tests) but state superintendents later exercised their leadership in defining standards and setting licensure requirements for prospective teachers (Stinnet, 1958; see also Sedlak, this volume).

While there have been efforts to maintain a distinction or differentiation between teacher licensure as a minimum condition for entry to the profession and certification as a standard for practice, the reality is that most people have continued to use the terms interchangeably (Cronin, 1983; Goodlad, 1990). However it is used, the term teacher certification has inspired a generation of activists to debate every aspect of the process of state certification and to question its effectiveness in defining high quality teaching (e.g. Asera & Chin, 2005; Ballou & Podgursky, 2000; Goldhaber & Brewer, 2002; Hanushek, 1997; Leigh & Mead, 2005; Rice, 2003; Rotherham & Mead, 2003; Walsh, 2001).

In these debates, some would increase the requirements and expectations for those seeking a teaching certificate; others would reduce the complexity of the current system, thus permitting greater access. On the one side are those who talk about certification as the means to increase teacher quality and contend that states, regional consortia of states, professional bodies, standards boards, or the federal government should exercise much greater control over who enters and advances in teaching. On the other side are those who contend that, if the current restrictions to teaching were reduced or even eliminated, schools and students would benefit by having a more diverse and talented teaching force.

Feeding the contention surrounding certification is the fact that state agencies must guarantee an adequate supply of teachers, while also ensuring that those teachers are well prepared. Some have argued that the responsibility for setting teaching standards must be separated and distanced from the state’s responsibilities for guaranteeing an adequate supply (Goodlad, 1990). The recasting of the state’s role in certification and the effort to assign standard-setting to professional entities is one of the important stories of the past 25 years, and the focus of the next section of this chapter.

One interesting aspect of the debate concerns the question of who should certify beginning teachers. Over time, teacher certification has moved from a local matter (often accompanied by locally-administered tests of teacher knowledge), to a matter for district or regional school superintendents to deal with, to state agencies. In the early 1900s, it was generally acknowledged that teacher certification was a matter of state policy and an integral part of the state’s responsibilities to offer a free and public education to all (Learned & Bagley, 1920). Eventually, professionals insisted that, as a profession,
teaching and teachers needed to be overseen by professional practices or standards boards. In 1946, with the creation of the National Commission on Teacher Education and Professional Standards (TEPS) by the National Education Association (NEA), the matter of teacher certification was raised to a level of national discourse, which led to the establishment of the National Council for the Accreditation of Teacher Education (NCATE) to accredit teacher preparation institutions. Yet, it would take another two generations before teacher certification would be attracting the attention of federal legislators and governmental agencies.

Today, the matter of teacher certification is highly contested. Distinctions between liberals and conservatives blur as proponents for using certification as a national tool to reshape the teacher workforce or to redefine the knowledge and skills of beginning teachers emerge from across the political spectrum. Those who insist that states increase the rigor of the certification process are drawn from the left and right, as are those who would minimize its importance and delegate to building principals the authority to hire teachers (regardless of their qualifications). These differences have taken on particular importance with the emergence of the National Board for Professional Teaching Standards (NBPTS) and, later, the American Board for the Certification of Teacher Excellence (ABCTE), as well as the introduction of the concept of “alternative certification.”

The founding of the NBPTS, through the efforts of a broad-based coalition of Republican and Democratic governors and other state legislators, the leadership of the two dominant teacher organizations, and an array of business and philanthropic leaders, created what the British call a quasi-non-governmental organization (quango) that had governmental involvement and support (in the ensuing dozen years, NBPTS would command nearly $100 million in federal appropriation) (Futrell, 2005). The NBPTS’s articulation of five core propositions and the development of standards and assessments for numerous fields and courses of study attracted the interest and support of politicians and the public.

At the same time, the rise of alternative certification in New Jersey gave rise to a totally different approach to standards setting—a movement that would eventually be embraced by most states and lead to a reconsideration of the concept of certification (Michelli, 2005). Almost from its inception, alternative certification was promoted by the U.S. Education Department, the Republican Study Council, and numerous state policy groups and national “think tanks” as a better way to attract people to teaching (Gursky, 1989). While it was fashionable to contend that one effort was directed at advancing an agenda of greater rigor and quality in teaching while the other was intended to promote ready access, the reality was that there was enormous disagreement—within both groups—regarding what beginning teachers should know and how that knowledge was best acquired.

Teacher certification is a means to an end, a device used to guarantee a set of minimum conditions for teaching. It is one of several policy tools available to policymakers to regulate or control the “flow” of persons into teaching. While discussion of certification prompts consideration of an idealized vision of a beginning teacher, policymakers inevitably retreat to a set of minimal standards or the essentials of what a beginning teacher should know and be able to do (Sykes, 1990). Program approval and professional accreditation are also tools used to maintain quality. During the last 25 years, there were considerable shifts on all of these policy fronts. Before describing those, however, let us briefly turn to the role of demographics in teacher certification and licensure.

**Demographics and teacher certification**

Aside from the political and ideological battles over teaching and teacher education, the factor that most influenced the debate on teacher certification was a demographic one,
that is, the prospect of a “looming” teacher shortage. As will be noted below, the report of the National Commission on Teaching and America’s Future (NCTAF, 1996) galvanized the policy community to act on matters of teacher policy. International comparisons and stagnating K-12 student test scores promoted enormous concern about teacher quality. One premise of the NCTAF report that received the most attention was the projected need for local schools and districts to hire 2.2 to 2.4 million public school teachers during the decade following the release of that report (NCES, 1999). In the face of this shortage, the authors highlighted the quality-quantity conundrum facing policymakers (Berry et al., 1998; Bradley, 1999; Darling-Hammond, 1996). In fact, President William Jefferson Clinton used his 1997 State of the Union address to highlight the need to both attract more people to teaching and to improve the quality of teachers in every classroom (The White House, 1997). Later, attention would focus on the need to find ways to stem the high attrition rates of beginning teachers, but policymakers rushed to address the shortage issue with incentive programs and loan forgiveness efforts designed to attract more people to teaching (Olson, 2003; Wayne, 2000).

CERTIFICATION BECOMES A STATE RESPONSIBILITY

Confounding observers of the certification scene has been the fact that state politicians and policymakers often call for higher standards for all candidates for teaching while reducing the requirements and lowering the barriers for some. Higher admission requirements (often in the form of GPAs, or SAT/ACT scores) are mandated for some while fewer prerequisites are expected of others in the name of alternative certification. State school boards (with most of the members elected in state elections or appointed by governors and/or state school superintendents) that control the certification process have found it difficult to maintain a uniform standard for all candidates. Particular teacher candidates are “advantaged” through abbreviated periods of training and reduced course requirements and shortened student teaching. In some states, where demand for beginning teachers has been the greatest, candidates are allowed to enter teaching with a few weeks of training—but then expected to accumulate professional development credits during the first years of teaching. It is the differentiation in requirements that strikes most teacher educators in “traditional” preparation programs as blatantly unfair.

Throughout this period, it appeared that many policymakers lacked understanding of the concept of teacher certification, in particular, the state’s role. For some on the political right, state certification was little more than “a cartel operated by the teacher unions and colleges of education to enforce monopolies in what amounts to restraint of trade . . . It has most surely impaired the quality of teaching in the classroom” (Heritage Foundation, 1989). Rather than state systems and bureaucracies being blamed for this condition, the focal point for attention was “traditional” teacher preparation programs. In fact, George H. Bush would run for President in 1988 on a platform that advocated alternative certification as the means “to remove unnecessary barriers to qualified individuals who want to teach.” Criticism of certification practices and teacher preparation was not limited to the political right. That same year, the National Governors Association (NGA, 1989) promoted alternative certification as a way to increase the number of teachers in mathematics and science.

The shift in authority for teacher education from the campus to the state occurred as campus-based education programs grew to meet the demand for PK-12 elementary and secondary school teachers. It was an explosion in numbers of beginning teachers that exceeded the capacity of state agencies to license individual teachers that resulted in the
franchising of the responsibility to campuses in the form of program approval. Programs could not operate without state approval and campuses subjected themselves to a state-approved curriculum for teacher education and were given the right to operate. Three decades later, the federal government recognized that prevailing policies and practices were failing to produce quality teachers. However, while there was widespread agreement that the federal government should assume a new role in teacher preparation or certification, two very different ways of accomplishing this goal emerged. One was the professionalization agenda that viewed teaching as a learned occupation requiring extensive preparation and long-term commitment. The other agenda—which we will call the deprofessionalization agenda—treated teaching as a short-term job requiring little preparation and much emphasis on subject matter knowledge.

Professionalism vs. deprofessionalism

Many who promote advanced standards for teaching and teachers claim the mantle of teacher professionalism. If teachers are to be accorded the respect and remuneration enjoyed by other professionals, they argue, standards have to be raised. Deprofessionalists posit that, while minimal conditions for teaching are necessary, these should not be so restrictive as to prevent the “best and brightest” from entering teaching (even if only for a short time). Their contention is that current policies restrict entry, often citing the success of Teach for America in attracting such college graduates. Both professionalists and deprofessionalists look to the states to modify the certification processes to either increase or decrease the requirements to teach, as each sees certification as the policy tool of choice to recast the American teacher.

Perhaps the thing that most promoted the debate about good teaching was the movement to create a standards-based school system with aligned elements and policy levers (Fuhrman, 1994; O’Day & Smith, 1986). In the drive to accomplish systemic reform, teacher certification was a tool to ensure that teachers prepared to teach in a state-approved teacher preparation programs would teach the state PK-12 student standards. Teacher education was viewed as an integral part of a statewide reform effort and subject to the conditions and expectations imposed by the state. This was an important theme of NASDTEC (1992), as they articulated new certification standards based on program outcomes and demonstrable professional practice. Teachers who completed state approved programs were expected to be able to teach the state’s approved course of study. Certification was a means to assess whether beginning teachers knew the material and were capable of presenting it to diverse youngsters in PK-12 schools.

But the policy proposal for teaching and teacher education most embraced by teacher educators—the professionalism agenda—has also been seen as an agenda in conflict with systemic reform. Professionalists have one set of expectations for beginning teachers, while those promoting a narrow conception of teaching as enabling all students to meet a prescribed set of outcome or performance standards often have another, and are more comfortably aligned at times with the deprofessionalists. Not only was the professionalization agenda out-of-step with the systemic reform efforts; it was also out-of-step with changes underway in higher education where college presidents were voicing their opposition to the organized teaching profession—most often represented by the teacher unions (Appleberry, 1994). Instead of embracing PK-12 teachers as peers, college presidents led a movement that blocked their involvement in specialized or professional accreditation, creating an alternative based on institutional mission rather than professional standards (Splete et al., 1996). Not surprisingly, these same forces gave little credence to the efforts to extend teacher preparation to five-year programs or to promote professional schools.
of education. Unlike other professional preparation programs—housed primarily in post-baccalaureate, research-oriented, status-seeking, and self-sustaining professional schools—teacher education remained a low-status, campus-wide, baccalaureate-level, teaching-intensive program that commanded few resources and even less respect (Labaree, 2004).

Debates about teacher education

Thus, entwined in discussions of licensure and certification is an on-going debate about the role and purpose of education schools. One conception casts schools of education as extensions of the state system of PK-12 schooling, and therefore such professional schools need to prepare teachers to “deliver” the state’s PK-12 curriculum. This conception is reflected in both how teacher education programs gain state approval and in the fact that 49 out of 50 states “house” teacher education in their PK-12 agency rather than the agency responsible for higher education. In this view, teacher educators are state employees with responsibilities to the state for ensuring that certified teachers teach to the PK-12 state standards.

An alternative view—one favored by higher education faculty—argues that schools of education are academic/disciplinary communities that reach beyond the state. This perspective positions teacher educators as university faculty who are charged with questioning the status quo—including the state’s education agenda—and with conducting research on curriculum, teaching, learning, and policy. If the state prescribes a course of study or a particular instructional approach, in this vision of the professoriate, the academy is expected to question its appropriateness or to pose alternative directions.

As this chapter was being completed, numerous studies and opinion pieces again raised serious questions about the role of education schools in preparing and supporting beginning teachers. Styled as “an obituary for education schools” (Finn, 2005), The New York Times headlined an expansive story, “Who Needs Education Schools?”, Finn observed that the author, Anemona Hartacollis (2005), concluded that the answer was “pretty much nobody.” He then observed that “education schools have lost their way: ‘social justice’ and high-minded theory now trump academic mastery and skills in classroom management, and alternate routes to the teaching profession have arisen to challenge the monopolistic hold of the ed school cartel.”

Finn and other neo-conservatives argue that teacher education and certification should be uncoupled, and that program approval should be abandoned. Competition between traditional and alternative providers, they posited, would lead to higher quality teachers. These debates about teacher education reform (and who should control access to teaching) are, at their heart, about professionalism and de-professionalism, regulation and deregulation (Allen, 2000; Cochran-Smith & Fries, 2001; Darling-Hammond, 2000). On the one hand, professionalists see certification, licensure, accreditation, and program approval—and the presumed higher status and renumeration that accompanies those things—as critical to providing both high quality and sufficient numbers of beginning teachers. Deprofessionalists decry these links, denouncing university-based teacher education, state systems of licensure, and national standards for advanced certification and teacher preparation. In particular, the critics raise questions about: (a) the epistemological and pedagogical underpinnings of contemporary teacher education, with outright attacks on constructivism, learner-centeredness, and critical theory; (b) the qualitative or narrative research paradigms used by education school faculty; and (c) higher education’s long dominance of the “market” for teacher education (Herring, 2001; Izumi & Coburn, 2001; Kozloff, 2001).
INCREASING CENTRALIZATION

With the 1992 reauthorization of the Higher Education Act of 1965, we began to witness a consistent effort to use federal policy to direct changes in certification and teaching policy more generally. That reauthorization strengthened the role of state agencies in setting certification standards, while recognizing NBPTS as a non-governmental organization that would assess advanced candidates. It also increased investment in state agency efforts to strengthen teacher licensure, while encouraging states to add alternatives to their strategies for teacher certification. Simultaneously, the newly-formed Teach for America, another quango (designed to attract the “best and the brightest” into teaching), was also garnering considerable financial and political support.

The blurring of roles and distinctions between federal and national entities and state and campus authorities for teacher education was driven by policy proposals that often came from professional organizations and national entities. When NCATE articulated a vision of a national system of accreditation in 1992 (one that called for merging state program approval and national specialized accreditation into an integrated system), college and university presidents protested. Shortly thereafter, a resolution of opposition from the American Association of Colleges for Teacher Education was lodged, as well as the creation of an alternative accreditation approach. The Teacher Education Accreditation Council (TEAC) was created by a group of liberal arts college presidents (through the leadership of the Council of Independent Colleges). With its long tradition of independence and many small liberal arts colleges, Iowa became a focus for debates about the appropriate role of national bodies in setting standards for teaching and teacher education. Central to those discussions was the issue of localism vs. centralism, the latter of which was rejected by the opposition. It was not a coincidence that this was also a time when all of specialized accreditation was under attack, with college and university presidents claiming that specialized accreditors served only the interests of a particular preparation program or professional school. NCATE’s standards and processes were the subject of particular concern, and leaders of various D.C.-based organizations offered support for TEAC or, at the very least, agreed not to take sides in what was cast as a contest between NCATE and TEAC.

Meanwhile, the NBPTS was expanding their assessments and vision. The development of new licensure tests by the Education Testing Service—the PRAXIS Series—reinforced efforts to conceptualize teaching as continuum of provisional to regular to advanced certification. The efforts to build an integrated national system of quality control, involving government and non-governmental agencies, as well as the private sector, offered much promise that a tightly coupled and aligned system of teaching and teacher education was possible through policy.

With the 1992 amendments to the Higher Education Act, the new Clinton administration embraced this agenda as well. Those who drafted the federal legislative proposals called for state plans that would lead to an integrated and coherent approach to attracting, recruiting, preparing and licensing teachers, administrators, and other educators so that there is a highly talented workforce of professional educators capable of preparing all students to reach challenging standards.

(Cohen & Smith, 1993)

Teacher certification continued to be the policy tool of choice while debates about centralism vs. localism (Strike, 1997) continued to swirl.
The NCTAF report and its influence on certification

Streams of work began to coalesce. The Carnegie Corporation agenda of the 1980s had been translated into a national agenda of reform and innovation. Goodlad’s (1990) *Teachers for Our Nation’s Schools* and the ongoing efforts of the Holmes Group (1986) kept teacher education at the forefront of efforts to transform teaching. But it would be the work of yet another quango that would serve as the dominant policy vehicle for change in the 1990s. The National Commission on Teaching and America’s Future (NCTAF) was formed in 1994. Linda Darling-Hammond led the efforts of the 26-person commission, funded by the Carnegie Corporation and the Rockefeller Foundation; the group took testimony, commissioned research products, and compiled research evidence. Its report, *What Matters Most: Teaching for America’s Future*, called for a “competent, caring and knowledgeable teacher in every classroom in America by 2006” and was clearly based on the professionalization agenda. Its call—for high quality preservice preparation, continuous professional development for all school personnel, autonomous professional standards boards, advanced teacher certification, strengthened professional accreditation, empowered teachers, professional development schools, and new forms of assessment of both students and teachers—was appealing to teachers and teacher educators alike and attracted considerable media attention.

The report was widely embraced by many policymakers at the state and federal level and resulted in federal investments of more than $30 million for its implementation. Those investments were paralleled by unprecedented grant activity by philanthropic foundations and enormous support for the report’s tenets. The NCTAF policy ideas were used in the half dozen legislative proposals introduced in Congress in 1998, relative to the reauthorization of teacher education programs in the Higher Education Act. The professionalization strategy—here based on the “three-legged stool” of accreditation, assessment, and certification—was popular with policymakers and was used at both the federal and state level to justify alignment across systems. Investments in the Interstate New Teacher Assessment and Support Consortium (INTASC) standards was championed, as was increased attention to the use of such work in a new system of performance-based teacher education accreditation introduced by NCATE. There was also widespread support for the use of the advanced certification standards of the NBPTS by state policymakers across the political spectrum (from Governors Tommy Thompson (R-WI) and John Engler (R-MI) to James Hunt (D-NC) and Gray Davis (D-CA)). It appeared to be a period of consensus and hope.

With the energy created by NCTAF, many anticipated that the key provisions in the NCTAF report would be incorporated into federal policy and replicated in every state, thereby serving to guarantee all children a competent and caring teacher. The localism-centralism tensions were resolved by the image of an overarching national system of quality assurance—shifting authority from local campuses to national entities—that was a “centralized-localized” system of professional controls and responsibilities. INTASC, NBPTS, and NCATE were increasingly aligned and there was much expectation that a national system of certification would emerge. NCTAF was a powerful instrument, and it should have resulted in substantial change.

The backlash

While the professionalization agenda was being embraced by the teacher organizations, other education associations, and by state and federal lawmakers, it was also generating enormous opposition. A well-organized opposition emerged, led by the Thomas B.
Fordham Foundation and a number of other right-of-center “think tanks.” The Fordham Foundation issued a “manifesto” that was based on a set of studies challenging the empirical legitimacy of each plank in the professionalization platform (Ballou & Podgursky, 1998; Ballou & Soler, 1998; Finn, 1997; Petrilli, 1998). Similarly, the Capital Research Center (1998) issued a policy brief that criticized NCTAF’s efforts:

in the name of “professionalizing” the teaching field, a well-organized cadre of national teacher education groups, working in close cooperation with the two major teacher unions, seeks to transfer the authority over teacher training and certification away from states and communities to private managerial agencies that are run by the cadre’s own members, who stand to gain much from a centralized teacher education system under their control and unaccountable to the public.

Better Teachers, Better Schools—a report issued by the Fordham Foundation—was even more appealing to both centrists and conservatives (Kanstoroom & Finn, 1999). Claiming that NCTAF was infatuated with “the romance of regulation,” these neo-conservatives argued for deregulation and much greater local discretion in teacher certification, preparation, and hiring. Asserting that “the regulatory strategy being pursued today to boost teacher quality is seriously flawed,” they argued for a minimalist approach. They contended, “The regulatory approach is also bound . . . to undermine the standards-and-accountability strategy for improving schools and raising student achievement.” “Simplify the entry and hiring process,” “Get rid of most hoops and hurdles,” “Open more paths into the classroom” (Palmaffy, 1999) were among their slogans.

The Fordham proposal to “widen the entryway, deregulate the processes, and hold people accountable for their results—results judged primarily in terms of classroom effectiveness” attracted considerable interest. With prominent educators from the first Bush administration lobbying Congress, much of the steam went out of the professionalization agenda. Various policy briefs and position papers led to a recasting of various Congressional proposals—from efforts to expand federal support for preservice teacher education to an emphasis on attracting “better candidates to teaching . . . who possess much more robust content knowledge.” Instead of an emphasis on capacity building for education schools, Congressional efforts emphasized alternative certification and non-traditional routes into teaching. Professionalization gave way to accountability as the dominant policy frame for teaching and teacher education.

A NEW AGE OF CENTRALIZED POLICYMAKING

It is important to understand that this combination of federal and state level policy proposals, when coupled with the profession’s own efforts to use quangos to assert dominance over teacher education policymaking, shifted the agenda away from institutional practices and academic controls to external or centralized policies. Those policies applied to both public and private education schools and carried with them enormous implications for education school deans and their faculties. Authority for teacher education shifted away from the campus and state agencies and toward national entities that formulated policies and practices.

While some would argue that centralization came with the Bush administration, centralized goal setting comes through most insistently in the various announcements of the Clinton U.S. Education Department. Repeatedly, Education Secretary Richard Riley
urged that extraordinary attention be devoted to issues of teacher quality. In one speech, he argued for the development of a common framework for teacher licensing, asserted that “we must make sweeping changes in how we prepare America’s teachers,” and claimed that too often colleges and departments of education are “sleepy little places” on the fringe of the campus “like forgotten stepchildren in our system of higher education” (Riley, 1999). He proposed a series of initiatives on teacher quality for college and university presidents including the appointment of a National Commission on Mathematics and Science Teaching for the 21st Century, chaired by former Senator John Glenn (D-OH), a national job bank for teacher recruitment, and a study of teacher tests by the National Academy of Sciences. With Clinton, teacher education became a national matter. Furthermore, as the dominant policy frame shifted from professionalism to accountability, colleges and universities came under increasingly intense scrutiny and were challenged in unprecedented ways to transform their teacher education programs. The regulatory focus of Sections 206 and 207 of the Higher Education Amendments of 1998 represented a sea-change in the role of the federal government as an overseer of teaching and teacher education.

The reauthorization of the Higher Education Act

The reauthorization of the Higher Education Act in a Republican-controlled Congress created a whole set of new accountability demands on teacher education. When Congress took up the matter of teacher education in February and March of 1998, it considered ten different legislative proposals. From these various proposals, a new Title II emerged to replace many existing programs with monies for states to revise teacher licensure requirements to increase expectations for teachers’ subject matter competence and to develop alternative routes. In the name of accountability, Congress imposed a set of stipulations for public reporting and disclosure. Senator Jeff Bingaman (D-NM) noted that education schools had access to more than $2 billion in federal student aid money and claimed that there “is overwhelming evidence that we are not getting the return on that investment . . . [and that] institutions with . . . egregious pass rates [on state teacher tests] are committing a form of fraud on entering students who aspire to be teachers” (Bingaman, 1998). While Bingaman was a supporter of the professionalization agenda, his efforts led to the addition of a host of accountability measures.

Parallel to the efforts in the Senate, Representative George Miller (D-CA) introduced legislation in the House of Representatives that called for:

- strengthening teacher licensing requirements to improve the academic knowledge of beginning teachers;
- holding colleges and universities accountable for preparing teachers competent in the academic content areas in which they plan to teach;
- calling upon states to strengthen their alternative route programs; and
- creating opportunities for on-going professional development of teachers and other school personnel to increase their knowledge of academic content.

The measure that passed the House (on a bipartisan vote of 414 to 4 on May 6, 1998) had been written by the House majority staff and included provisions that required programs to demonstrate 70 percent pass rates on subject matter test for their graduates, as well as calling upon governors to “provide[e] prospective teachers alternatives to schools of education through programs at colleges of arts and sciences or at nonprofit organizations.”
The Senate would add language to mandate the establishment of a national annual report card on the condition of teacher education. The U.S. Secretary of Education was to annually report on the qualifications of beginning teachers and show the national mean and median scores of these teachers on the standardized tests used for teacher licensure and certification. Also mandated were state and institutional report cards on the quality of teacher education. The college or university report card would include the following:

- passing rates of graduates on the teacher certification and licensure assessments of the state in which it is located;
- passing rates in comparison to the state’s average pass rate;
- the number of students in each program, the average number of hours of supervised practice teaching, and the faculty-student ratio used in clinical experiences;
- an indication of whether the program is state-approved and nationally-accredited; and
- whether the program has been designated as low performing by the state, that is, failing to meet a baseline pass rate for its graduates on state licensing tests (Paige, 2002).

College presidents and their organizations rallied in opposition to the Bingaman-Miller provisions, particularly those connecting student aid eligibility to teacher candidate success rates on state tests, as well as those making NCATE accreditation mandatory. One leader described the political climate as “poisonous” and the mandates as “regulatory intrusion” (Magrath, 1998). While provisions concerning institutional eligibility for student financial aid and the mandating of NCATE accreditation were withdrawn (in exchange for the promise that the higher education community would address the matter of the quality of teacher education), the other accountability provisions were passed.

Following the enactment of the Higher Education Amendments of 1998, much of the focus of the Washington higher education policy community shifted to rule-making relative to the implementation of the amendments. This process was remarkably free of controversy. Regulations were drafted and shared with the higher education community. Teacher education was the focus of the greatest controversy as regulations were written to implement Section 207 of Title II of the Higher Education Act that sought to describe a methodology for gathering the required accountability data and generating common definitions for terms used in the mandatory annual state and institutional reports (e.g. credential, pass-rate, teaching candidate, etc.). Given the statutory requirement to seek input from states and colleges and universities, the National Center for Education Statistics (NCES) formed a consultative committee of academics, state officials, and interest group leaders that contributed to a report that appeared in the Federal Register.

Control of teaching and teacher education had clearly shifted to Washington. The newly-established national rules conceptualized teacher education as an all-campus responsibility and held universities or presidents responsible for program quality. The reliance on a series of report cards and teacher tests to drive Congressionally-determined reforms was consistent with forms of accountability previously used in states and applied to PK-12 schools. While these accountability provisions were mandatory, they were also unfunded, resulting in increased costs for teacher education. They also were threatening, as they imposed fines and sanctions for those who failed to report the relevant data.

Higher education’s rejection of the professionalization agenda was most evident in a statement of principles issued by the American Association of State Colleges and Universities (AASCU) and the appeal for an alternative accreditation agency for teacher
education. To many, AASCU’s policy statement—calling for states to reassert their responsibilities for licensure and program approval—represented a bald rejection of the teacher professionalism movement (Appleberry, 1994). It is also important to note that these shifts took place in a broader context in which teacher unions were attempting to organize college faculties and university officials feared that the quangos—NBPTS, INTASC, NCTAF, NCATE—were largely controlled by the National Education Association and the American Federation of Teachers and, therefore, the “enemy.”

College and university leaders, education school deans and their faculties began to recognize that a profound shift in responsibility for teacher preparation and teaching policies was underway. Whereas teacher education had become a state enterprise in the 1970s and early 1980s, teacher and teacher education policy was—in the late 1990s—increasingly national and “controlled” by the profession. Whereas teacher education had been a decentralized and often dispersed series of programs across a college campus, the 1998 amendments made teacher education a primary responsibility of the university president. With the encouragement of government authorities, responsibility for teacher education moved from university and college presidents and provosts having de facto responsibility for the conduct of teacher education to university leaders having a de jure responsibility for its success. There was also a shift from state to federal controls which heightened accountability expectations. The traditional responsibilities held by state agencies for teacher education, through program approval and beginning teacher licensure, was gradually shifting to national and professional authorities. Some have described this move as the “federalization” of teacher education policy. While embraced by an array of stakeholders across the political spectrum, it would take the policies of the Bush administration to solidify it.

The education agenda of the Bush administration

In his campaign for the presidency in 2000, G. W. Bush repeatedly pointed to the “near miraculous progress of Texas schools in reducing dropouts and increasing achievement,” offering it as the model for American education (Haney, 2000). Bush insisted that the miracle was a result of changes in teacher certification, the expansion of alternative certification, tenure reforms for teachers, and the creation of differentiated staffing and bonus pay programs for teachers in high need schools. In addition, there was a heavy emphasis on using strategies “grounded in scientific research” (Fenoglio & Cannon, 2001).

During the first month of his presidency, Bush made education his first and most visible initiative. He introduced an education plan that he suggested would “overhaul federal education policy” (Milbank, 2001). The president’s plan closely resembled what he had promised on the campaign trail and called for increasing student accountability, focusing on “what works,” reducing bureaucracy, increasing flexibility, and empowering parents. The president’s plan called for states to “select and design assessments of their choosing” for all students in grades three through eight, and required schools to publicly report results disaggregated by race, gender, English language proficiency, disability and socioeconomic status. States were to be more accountable for student performance.

In a climate of intense partisanship and attention to electoral politics, the one piece of domestic legislation that was enacted by the Congress during the first two years of the Bush administration was the No Child Left Behind Act (P.L. 107-N110, NCLB). In a rare display of bipartisanship, both chambers and both parties completed work on the education legislation, sending it to Bush for his signature by the end of December 2001. Though opposed by most of the organized education community and considered too
intrusive or too flawed, in the aftermath of the September 11th crisis NCLB was signed into law on January 8, 2002. It was an act that only a Republican president could get passed because of its challenges to localism and local control (Alvarez, 2001; Beadle, 2001; Cardman, 2001).

The final version of NCLB was opposed by the teacher organizations, school board representatives, the National Conference of State Legislators, and the American Association of School Administrators. Opposition focused on “the unfunded mandates” and the lack of flexibility in the bill for schools and school districts. Virtually everyone agreed that the new law was both the most ambitious and most intrusive piece of educational legislation since the original enactment of the Elementary and Secondary Education Act of 1965 (ESEA), with both liberals and conservatives praising the intent but voicing their disapproval about the federal intrusion into local education policymaking. Conservatives argued that NCLB gives too much control to Washington, while liberals contended that it does little to close the discrepancy between rich and poor schools or address the achievement gap. While there were significant differences between the House and Senate with regard to teacher education and professional development (e.g. over definitions of “high quality” teachers and whether these should apply to both beginning and experienced teachers), these differences were resolved very early and the final bill had much of consequence for education schools and teacher education. Just one aspect of this would be that professional development provided with ESEA monies should be based on “scientifically-based” research. Also, traditional sources of grant support from Washington would now be combined with current and new school-based professional development monies and education schools would have to redirect their energies to acquiring monies from local education authorities.

NCLB and teacher policy

The other reality of this legislation was the ascendancy of teacher quality as a guiding principle for public policy formulation. Teacher quality dominated the policy debates regarding education and was at the core of NCLB. There were cross-sector conferences on teacher quality. Business leaders issued reports on ways to achieve it, foundations built program agendas and sponsored collaboratives, state policymakers enacted legislation, “think tanks” offered alternative strategies. Indeed, much of the Bush education agenda during the first term was built on the assumption that high quality teachers were essential to realizing education reform.

The belief that highly qualified teachers were the essential element of any strategy to help PK-12 students learn became widespread. According to the Bush administration, highly qualified teachers possessed subject matter competence in core academic subjects and are able to significantly raise PK-12 students’ achievement. This definition was premised on evidence derived from the “value-added” assessment model of William Sanders (e.g. Sanders & Horn, 1998; Sanders & Rivers, 1996). Value-added methodology was embraced by numerous groups and many in the philanthropic community as a means for reforming teacher education professional development, licensure, certification, and accreditation. For instance, The Teaching Commission—an independent entity convened by former IBM Executive Lou Gerstner—described the value-added methodology as “the most promising technique available,” calling for “some version of the ‘value-added’ method [being] used to measure student achievement in every school” (The Teaching Commission, 2004).

The Bush administration used teacher certification as a policy tool to change teaching and encouraged states to align state licensure provisions with NCLB and to gather
information on highly qualified teachers, with a particular focus on teacher’s verbal ability and content major as the indicators of high quality. NCLB defines a highly qualified teacher (HQT) as:

[A college graduate who] has obtained full State certification as a teacher (including certification obtained through alternative routes to certification) or passed the State teacher licensing examination, and holds a license to teach in such State [and who has] not had certification or licensure requirements waived on an emergency, temporary, or provisional basis.

Many have attempted to interpret the law to put a premium on subject matter knowledge at the expense of almost everything else. These efforts have brought criticism from various groups, including the Education Trust, a centrist advocacy group which has often been described as the primary source for most of the ideas in NCLB. For example, Education Trust (2003) issued Telling the Whole Truth (or Not) About Highly Qualified Teachers, which condemned federal and state efforts to gather data and information on the condition of teaching. The group’s president, Kati Haycock (2003), suggested that the teacher quality provisions have at various times been “ignored, misinterpreted, and misunderstood,” contending that the Education Department prompted a lowering of standards at the state level by ignoring the challenge of placing high quality teachers in schools in need of improvement. The Education Trust document paralleled an earlier General Accounting Office study on teacher quality entitled, No Child Left Behind Act: More Information Would Help States Determine Which Teachers Are Highly Qualified, which reported that states needed much more information about ways to evaluate the subject matter knowledge of current teachers (Bright & Harmeyer, 2002). That study also found that there was little consensus on what constitutes effective or high-quality teaching, and that various studies indicated that teacher effectiveness is dependent upon variables such as years of experience, advanced degrees, teaching assignments (in-field or out-of-field), state certification, preparation and professional development, teacher scores on standardized tests, and verbal ability. Despite the fact that studies sponsored by the U.S. Education Department consistently have failed to narrow the range of indicators of teacher effectiveness, policymakers continued to insist on the need for highly qualified teachers.

The U.S. Education Department vigorously responded to Haycock’s criticism, citing a number of initiatives including the new Teacher Assistance Corps, a Toolkit for Teachers, projects such as American Board for the Certification of Teacher Excellence, the creation of the What Works Clearinghouse, and technical assistance from the Council of Chief State School Officers and the National Association of State Directors of Teacher Education Certification to provide guidance in meeting the law’s requirements.

Given the absence of better indicators of highly qualified teachers, recent policy has focused on two measures: scores on standardized tests of subject matter knowledge and degree attainment in a particular core or academic subject. With the support of dozens of advocacy groups across the political spectrum, the Bush administration is likely to continue to press the case for highly qualified teachers using this narrow conception.

The Bush administration sought to realize its vision of education by using a blend of rules and regulations, admonishments and funding strategies. In particular, they have promoted greater access to teaching as the way to improve teacher quality, embracing both “competitive” and “alternative” certification as policy tools. They also championed greater regulation of “traditional” teacher education (with institutional reporting of candidate scores on state administered tests and mandates to assess the achievement of
program graduates’ K-12 students) while promoting efforts to bypass teacher education (through sponsorship of on-line teacher preparation programs, for example, Western Governors University, for traditional aged college students, Troops to Teachers programs for military personnel, and Teach for America for college graduates from prestigious colleges). The results are that Congress and the U.S. Education Department currently hold traditional programs to higher levels of accountability while supporting initiatives that reduce—if not eliminate—those standards for alternative route programs.

The Bush agenda for teacher education

The Bush administration used a surprising array of policy tools to push for the reform of teacher education as well. Reports of the Education Secretary cast aspersions on traditional teacher education and promoted alternative routes. Seventy-seven million dollars was invested in conservative efforts to by-pass “traditional” teacher education and promoted a host of new efforts for professional development and teacher education (Bradley, 2003). Nearly 3 billion dollars was awarded to states and local school districts to fashion new models of teacher education. These efforts were reinforced by other actions that were included in both the reauthorization of Individuals with Disabilities Education Act (IDEA) and in the various proposals to reauthorize the Higher Education Act. If fully enacted, these policy proposals would redirect existing federal support for teacher education to other providers, including local school districts, and seriously impair the capacity of education schools to prepare and support sufficient numbers of high quality beginning teachers.

The most comprehensive statement of those policy proposals was contained in a seriously flawed report to the Congress by the U.S. Department of Education entitled The Secretary’s Annual Report on Teacher Quality: Meeting the Highly Qualified Teachers Challenge (Paige, 2002). The report offered four far-reaching policy proposals:

- support the development of new models of “teacher training” that are “local,” “based on the best alternative route programs of today,” and “produce teachers with those skills that are in high demand”;
- support state initiatives to end the “exclusive franchise” of schools of education and to curtail the “shocking number” of mandated education courses or assist state efforts to uncouple education school courses from state licensure, making “attendance at schools of education . . . optional”;
- help states to “streamline” licensure requirements to place a premium on verbal ability and content knowledge, develop new and “challenging assessments” for teacher candidates, and require “content area majors”; and
- promote state efforts to shift authority for determining the qualifications of beginning teachers “from state certification officials . . . to local school principals.”

While these policy proposals were largely drawn from an earlier report issued by the Progressive Policy Institute (Hess, 2001), the proposed policies represented the direction the Bush administration intended to take. The institute’s report also served as the frame for the March 2002 White House conference on teacher preparation. Fundamental where a set of claims about research on and practice in teaching and teacher preparation, including:

- rigorous research indicates that verbal ability and content knowledge are the most important attributes of highly qualified teachers;
• there is little evidence that education school course work leads to improved student achievement;
• today’s certification system discourages some of the most talented candidates from entering the profession while allowing too many poorly qualified individuals to teach; and
• alternative routes to certification demonstrate that streamlined systems can boost the quantity of teachers while maintaining—or even improving—their quality.

The flaws in Paige (2002) were legion. For an administration that had repeatedly pressed for research evidence to be “scientifically-based,” little such evidence was used to substantiate the report. The studies that were cited had a decidedly ideological bent, were primarily funded by a single source, and failed the requirement for being peer reviewed or relying on randomized experiments. Further, the report—which was ostensibly about the performance of education schools in meeting HEA Title II, Sec.207 requirements—gave little attention to the matter of candidate performance or the pass rates of candidates enrolled in education schools. It essentially dismissed the mandate to do so, citing the low quality of the tests used. Paige (2003) later asserted that low cut scores and “10th-grade level” tests characterizes the current system, arguing that “standards for teachers, in far too many states” are “extremely low.”

Meanwhile, the Bush administration also signaled its intent to influence state boards of education and other state agencies that control teacher licensure and certification to adopt policies more conducive to the provisions of NCLB. Uncoupling courses in teacher education from state licensure requirements was one goal. Described as an alternative to regular or traditional teacher certification, competitive certification was offered as effective means for ensuring a highly qualified teacher workforce. In effect, competitive certification promotes many different certifications (by states, professional standards bodies, local education agencies, NBPTS and ABCTE, teacher organizations and others), ceding to local school officials the authority to hire those they feel are best qualified to meet the staffing needs of their local schools. Competitive certification would come to be widely debated but to date has few adherents and even fewer adopters.

The Bush administration also set out to create a genuine alternative certification program that would be national in scope and serve as a substitute for state licensure, the American Board for Certification of Teaching Excellence (ABCTE). Patterned after the National Board for Professional Teaching Standards, this new quango was formed to develop a new licensure and advanced certification test for both beginning and practicing teachers. This was to be a non-state, independent agency to which states would have to cede authority to test and then certify beginning teachers using standards and assessments based not on state but rather national standards.

ABCTE was one of the most ambitious Bush administration proposals, as well as one of its most controversial. In contrast to teacher tests developed by the Education Testing Service, the National Evaluation Systems, and other testing houses, this new assessment would not be aligned to specific teacher standards of a particular state but would instead be based on a set of generic standards (derived from teacher standards in Virginia, California, and New York) and a set of guiding principles derived from a carefully constructed knowledge base on teacher education. An initial grant of $5 million was made to the Education Leaders Council to undertake this work, which was followed by a $35 million non-competitive discretionary grant to the National Council for Teacher Quality to advance this alternative (Cardman, 2003).

The initial focus of ABCTE was on beginning teachers, offering college graduates—with at least a bachelor’s degree—the opportunity to earn a Passport Certificate if they
possessed written language skills, a fundamental knowledge of teaching, and could pass a criminal background check and a series of examinations demonstrating subject-matter proficiency, as well as document a high quality classroom-based field experience. ABCTE would also attempt to compete with NBPTS by offering a Master Teaching Certificate for experienced teachers who passed “a rigorous test and [had] a track record of teaching excellence as demonstrated by student achievement.”

ABCTE promoted the use of its assessments by seeking the endorsement of state legislatures, boards of education, and professional standards boards. ABCTE would gain adherents among Education Leadership Council members in a half dozen states in its first years of operation and—after changing testing contractors—launched a vigorous campaign for acceptance and adoption (Bradley, 2003). Its importance, for our purposes here, was less its structure and aggressive campaign for acceptance and more the fact that ABCTE represents a genuine effort by the Bush administration to create an alternative to state licensure and, like NBPTS, suggested a profound shift in the practice of certification.

The underlying logic was that, since the state had to guarantee an adequate supply of beginning teachers, its certification policies were dictated not by matters of high quality but rather by the exigencies of supply and demand. If demand was high and supply was low, then states recast their teacher certification policies to promote greater access to teaching. The Bush administration challenged state authority and promoted reliance on non-state entities to certify beginning teachers.

ABCTE carried with it enormous consequences for education schools; it was one of the most thoughtful and imaginative ways presented by neo-conservatives to remake teaching and the teacher workforce. Just as they were promoting the idea of competitive certification, so also were they endorsing the concept of competition between specialized accreditation bodies. While officials in earlier U.S. Education Departments had supported the idea of multiple accreditors for a particular sector or professional preparation area, this had not occurred in teacher education because of the absence of such an entity. The Bush administration encouraged the development of the alternative teacher education accreditor by granting federal funding and recognition to the Teacher Education Accrediting Council in October 2003.

The technician teacher argument

Finally, members of the Bush administration pressed for a different type of teacher to staff the schools. Grover R. Whitehurst, the Director of the Institute for Education Sciences, advanced the idea that there were two types of teachers: long-term teaching professionals who were prepared in education schools to assume numerous roles in promoting the learning of students and technicians who implement prescribed learning modules and training. Whitehurst suggested that the success of NCLB was dependent upon having enough “good enough teachers” who were skilled at teaching a lesson, maintaining discipline, and ensuring that PK-12 students do well on whatever performance measure used. Whitehurst contended that professional teachers present a costly burden to high-needs schools; technician teachers were more cost effective.

CONCLUSION: COMPETITIVE CERTIFICATION AND POLICY FOR TEACHING

The argument here is that the proliferation of quality assurance and control policies and bodies for teachers and teacher education is a legacy of policies broadly embraced by the
teaching profession (and teacher educators) in the 1980s and 1990s. NBPTS and NCATE, NCTAF and national standards-setting bodies were hailed as extra-state, professional agencies to control access to and promote high quality in teaching. The idea that a competing set of such agencies would emerge (often with competing agendas and philosophies) was never anticipated. The reality that teaching and teacher education face in 2006 is far different that what was anticipated 25 years ago. Neo-conservative policies that champion competition, free-markets, and deregulation exploit those efforts and seek to refashion teaching policy by relying on competitive certification. With policy for education schools increasingly being set in Washington, education deans and faculty have to be particularly concerned with the attitudes of Congress and White House. In a study commissioned by AACTE and the American Council on Education, it was found that members of Congress are “increasingly angry toward schools of education” and are insisting that they demonstrate a commitment to both high quality and “improved interaction with K-12 schools and follow-up with their [graduates] who have become teachers” (Gunderson, 2003).

Changing attitudes and shaping policy is imperative. It is particularly important in 2005 as Congress continues the process of reauthorizing the Higher Education Act of 1965 (PL 105-244)—with the explicit goal of connecting HEA to NCLB and renewing the Individuals with Disabilities Education Act (PL 105–17). What all of these pieces of federal legislation have in common is the opportunity for federal policymakers to recast teacher certification and reinforce policies and practices that appear to undermine education schools.

These developments lead to the unmistakable conclusion that the Bush administration is determined to greatly reduce the influence of education schools in teacher preparation and certification. Some see this as an intentional effort to put the teaching profession at risk, to undermine the professional status of teaching, and to dismantle the conditions for professional work. These efforts include the well-orchestrated effort to sponsor alternative routes to the classroom, to redefine “highly qualified teachers” as teachers with subject matter knowledge alone, and to denigrate the research and training undertaken by education researchers. It is both an overt challenge, with few education schools exempted from attack, and an implicit threat to everything that education school faculty believe and understand about good teaching and learning.

For 25 years, many have worked to create a profession of teaching. The codification of a knowledge base of teaching; the expansion of the life-space for the preparation of professional practitioners, role differentiation, and opportunities for advancement and increased responsibility; the appeal for autonomy over practice are important elements of this professional agenda. The NBPTS, INTASC, and NCATE were the policy vehicles to be used to realize this agenda. In the 1990s, NCTAF reinforced earlier efforts of the TEPS Commission and the Bicentennial Commission of the AACTE. By the late-1990s, there was a surprising degree of consensus and uniformity represented by these various agencies and efforts, and the government was poised to embrace this agenda.

The fact that neo-conservatives were able to derail these efforts and promote an alternative agenda—one of public accountability, deregulation, competition, and reliance on market forces to control teaching and teacher education—is remarkable. They shifted the dialogue from one that focused on professional standards and progressive ideas—with attention to the role of school in providing “access to knowledge” and “enculturating the young into a political democracy”—to an agenda that centered attention on “good enough” teachers (Finn et al., 1999; Goodlad, 1990; Whitehurst, 2003). At the same time, the Bush administration focused on recasting teacher certification from a “safe to
practice” criterion to a matter of “high quality.” It sought to move certification from a narrowly construed state responsibility to an array of national entities. Ultimately, its efforts were to give school principals greater choice in the selection of beginning teachers, although the connection between this practice and teacher quality was tenuous at best. While professional consensus was the basis for both the INTASC and NBPTS standards for teachers and NCATE’s teacher education standards, the efforts of the neo-conservatives have undermined that agenda and put the profession of teaching at even greater risk.

The solution? Education professionals have to embrace an agenda of teacher effectiveness and promote a common set of performance standards or their voice will be lost in the debate. Teacher effectiveness is measured by the success of PK-12 students in scoring well on tests of student achievement. Gaining consensus on measures that promote such teaching is a necessary starting point in any long term discussion of the role of teaching and teaching policy for America’s schools. Absent serious effort at rebuilding a profession of teaching, teaching will be cast as a skilled occupation or semi-profession and will lack, therefore, public status and accord. Using teacher certification as a policy tool to promote PK-12 student learning as the ultimate teacher role is the place to begin.

The surest, quickest way to add quality to primary and secondary education would be addition by subtraction: Close all the schools of education. (Will, 2006)

INTRODUCTION

We live in an age of lively discussions concerning the value of “traditional” teacher education, which includes teacher preparation programs, teacher certification and licensing practices, and accreditation processes for programs. Teacher education programs are “intellectually barren,” teacher educators are “arrogant” and “inept” (Hess, 2005). “There is a built-in institutional vapidity in ed schools” (Rochester, 2002). Refrains echo past criticisms leveled at the teacher education enterprise. Concerns like these were raised at least as far back as the 1930s, gaining a great deal of public exposure in the 1950s and 1960s with books like Bestor’s (1953) Educational Wastelands, Lynd’s (1953) Quackery in the Public Schools, Smith’s (1949) And Madly Teach, Conant’s (1964) The Education of American Teachers, and Koerner’s (1963) The Miseducation of American Teachers. Koerner (1963) concluded that education school courses were “vague, insipid, time wasting adumbrations of the obvious” (p. 56). And Bestor (1953) proclaimed that there was a “preposterous overemphasis upon pedagogy that produces teachers who can talk glibly about how to teach, but who know too little about any given subject to teach it satisfactorily.”

The teacher establishment does not always take such criticism well. Defenders of teacher education characterize the critics as “an alliance of thugs” or “marketeers” who seek to turn children into “sources of profit” and who are “at war with the public schools” (Hess, 2005); accusations are made about misrepresentations and misinterpretations of research and practice. Teacher educators and critics seem equally ready and likely to hurl accusations.¹ In so doing, important differences are obscured: critics are cast as political conservatives who do not care about social justice, for example, as assumptions about one’s political values are considered coterminous with one’s concerns about education and teacher quality.² Teacher educators are lumped together as a unified bloc of subject matter-deficient worshippers at the altar of progressive ideals who care only about process and never about content.
And everyone seems to want a piece of the action. The Secretary of Education has weighed in with reports on teacher quality (U.S.D.E., 2002, 2003); the National Board for Professional Teaching Standards jockeys for power in defining and certifying teacher excellence. States attempt to take over control of the content of teacher preparation (Prestine, 1991); the federal government attempts to close colleges of education and open up alternative routes into teaching, such as the certification available through the American Board for the Certification of Teaching Excellence (ABCTE) which received considerable financial support from the federal government under the Bush administration. Reports are issued and studies funded by the Thomas B. Fordham Foundation, American Federation of Teachers, Department of Education, American Educational Research Association, National Council on Teacher Quality, and National Academy of Education. Conferences are sponsored by think tanks, including the American Enterprise Institute, Hoover Institute, Brookings Institution, Progressive Policy Institute, and Manhattan Institute. Columnists from the New York Times (Kristof, 2006) and Newsweek (Will, 2006) have thrown in their two cents as well. The most recent of these reports, Levine’s (2006) Educating School Teachers, while largely reiterating previous critiques and analyses of the problems of teacher preparation, drew enough attention to remind us all that teacher education remains promising fodder for critique in the profession, public, and press.

Our aim is to understand and map the critics and their concerns. Thus, in this chapter, we explore two questions: Who are the critics? What are their concerns? By examining the contemporary jurisdictional challenges to teacher preparation and certification—that is, the different individuals, groups, and institutions that struggle for power—we hope to gain insight into the social arrangements and transactions of power that shape, build, and redefine who controls the preparation and licensing of teachers.

Our approach, albeit more modest, is inspired by Bourdieu’s (1988) canonical work on the French higher education system, Homo Academicus. In laying out this argument, we aim to develop a useful conceptual framework that would allow a better understanding of the teacher education field, both for challengers and defenders. In this sense, we face a problem similar to the one Bourdieu faced as he tried to understand—as an insider—the ways in which different groups and individuals struggled for power and control in a field that he himself belonged to. Bourdieu’s attempt to portray his academic community led to harsh criticism from many of his colleagues. It is our hope that conceptualizing the debates over teacher education as a power struggle within what Bourdieu (1985, 1988; Bourdieu & Wacquant, 1992) has called a “social field” will allow for a more “objective”—or, at the very least, a somewhat distanced—evaluation of contemporary activity around teacher licensing and certification. In the midst of a heated and divisive struggle, where both challengers and defenders fight fiercely, at times presenting intentionally-biased research and evaluations, there is a clear need for an analysis that takes one step back in an attempt to provide—perhaps—a more “balanced” approach. Here we take a first step by mapping out the challengers and their critiques. While it is equally important to consider the establishment’s responses to those critiques, we leave that analysis for later (Tamir, 2006; Wilson, in progress).

TEACHER EDUCATION AS A SOCIAL FIELD

Let us start by introducing the notion of the social field, its general structure, logic of action, and components. According to Bourdieu and Wacquant (1992), the social space is comprised of “configuration of objective relations”: 
These positions are objectively defined, in their existence and in the determinations they impose upon their occupants, agents or institutions, by their present and potential situation (situs) in the structure of the distribution of species of power (or capital) whose possession commands access to the specific profits that are at stake in the field.

(p. 97)

In other words, a field is a space where social agents—individuals, groups, and institutions—interact, work, and struggle over power. These social agents possess a shared set of understandings, beliefs, values, and norms that constitute the logic and rules of the game for that field (Bourdieu, 1985).

These shared understandings of the field by social agents differ from one field to another. However, one thing that is always shared among social agents of a given field is the importance they ascribe to their field and to the importance of continuing to manufacture the products of their field. Artists, for example, share a general belief that their work matters. There is also the self-serving aspect, that is, all members of a field are invested in and thus dependent on the field thriving. This, however, does not mean that they do not struggle fiercely among themselves. The same is true for social agents who operate in the field of teacher education. They all believe that education is important and that teacher education is essential. They differ, however, in their beliefs about the nature of effective teacher preparation. We return to the question of how much “shared” belief, values, and knowledge the field of teacher education needs later in our discussion.

The orthodoxy

So who might be in this network of relations in the social field of teacher education? We will begin with the “teacher education establishment.” There is the American Association of Colleges of Teacher Education (AATE), created in 1948 from the merger of six teacher educator associations, as well as the Association of Teacher Educators (ATE), which was founded in 1920, and includes members from over 700 colleges and universities, 500 school systems, and most state departments of education. The evolution, as well as past and current history of those collectivities, is explicated by Angus (2001), Imig and Imig (this volume), and Sedlak (this volume).

But not all teacher educators align themselves with those communities, and so we need to add also the Holmes Group, a consortium of research universities concerned with the state of teacher education in the wake of the publication of A Nation at Risk (National Commission on Excellence and Education, 1983), which later became the Holmes Partnership in 1996, and the American Educational Research Association (AERA), especially Division K, Teaching and Teacher Education, which attracts faculty from across teacher education programs who are often interested in the practice of and research about teacher education. We might then add the National Council for Accreditation of Teacher Education (NCATE) and the Teacher Education Accreditation Council (TEAC), the two accrediting institutions within teacher education, as well as state departments of education, which make decisions about individual teacher certification and licensure, as well as program accreditation. Most state departments of education are staffed with personnel who have been trained as educators and thus are naturally aligned with the education establishment. Critics often understand the establishment as those individuals who embrace progressive education ideas (Hirsch, 1996; Null, 2006; Ravitch, 2000). However, there is considerable variability in how aligned state department personnel are with
university teacher educators or with K-12 teachers and administrators. Sometimes these groups collaborate extensively and share common ideas and ideals; at other times, they are at odds, struggling amongst themselves for power. This may be increasingly the case with the growing interest of states and the federal government in regulating and controlling public education and teacher quality in particular (Prestine, 1991; Ramirez, 2004; Tamir, 2006). The fact that state departments, as well as other groups, shift position helps remind us that Bourdieu’s notions of a social field, with its orthodoxies and heterodoxies, are fluid, ever-changing.

Let us pause and consider this partial mapping of relations and groups. These institutions include many individuals who are considered members of the traditional teacher education establishment: university-based teacher educators; state department staff who license and certify teachers; accreditation organizations; leaders of the professional associations and movements, like David Imig and Sharon Robinson from AACTE, Art Wise from NCATE, Judith Lanier, Frank Murray, and Robert Yinger from the Holmes Group and later Holmes Partnership, as well as Murray’s leadership of TEAC. There are also networks like the Urban Network to Improve Teacher Education (UNITE), as well as alternative preparation programs created by the orthodoxy, including the DeWitt Wallace-Reader’s Digest Fund’s Pathways to Teaching Careers Program.

The network fills in quickly as one also considers foundations and other groups that fund work by these organizations, other scholars and advocates who organize efforts to improve teaching and teacher education, and the like. So, for example, Linda Darling-Hammond, who has long collaborated with Art Wise, is closely associated with the professionalization movement in teaching through her work in organizations like the National Commission on Teaching and America’s Future (NCTAF, 1996, 2003). There is also Lee Shulman, current president of the Carnegie Foundation for the Advancement of Teaching (CFAT), whose ideas of teachers’ professional knowledge greatly influenced the development of the National Board for Professional Teaching Standards, as well as the standards and assessments developed by the Chief State School Officers (CCSSO) through their Interstate New Teacher Assessment and Support Consortium (INTASC). Other teacher education leaders, like Marilyn Cochran Smith, Robert Floden, Pamela Grossman, and Gloria Ladson-Billings, exercise influence through holding offices in and winning awards from professional organizations like the American Education Research Association and AACTE. There is also the complication that the ideas and arguments of these actors shift over time. While portraits such as that offered here momentarily “freeze” an ever-evolving landscape, this ought not be construed as a portrait of a static field.

And then there are the professional journals acting as the organs for ideas about teacher education, including *Action in Teacher Education* (sponsored by ATE, the sponsor of this handbook), the *Journal of Teacher Education* (sponsored by AACTE), and the *International Journal of Teaching and Teacher Education* (TATE), as well as other journals like *Educational Researcher* and the *American Education Research Journal* (AERJ) in which many AERA members publish. And, as previously mentioned, there are the state level organizations, which also have their own journals.

While these are certainly not the only participants and organizations within this community (we apologize to any group or individual who is not named; our intent here is to evoke—not inventory—the character of the field), these networks of people, institutions, and professional organizations represent what Bourdieu (1984, 2005) would call the “orthodoxy” of the social field, the aggregation of individuals, groups, and institutions that hold and preserve a coherent line of ideas, interests, practices, and visions that dominate a given field.
The heterodoxy

While these agents might account for the bulk of the teacher education establishment, there are other actors—what Bourdieu (2005) calls the “heterodoxy”—who also have strong opinions about teacher quality, preparation, and certification. According to Bourdieu, these agents too have a stake in the field, but they do not necessarily possess the shared norms and assumptions—Bourdieu’s (1986) “cultural capital”—that are used to legitimate authority in the field. The heterodoxy, then, attempts to challenge the status quo.

Who are these “others?” First, there are the alternative routes that have been established by school districts and states. There is also the National Center for Education Information (NCEI) and the newly established National Center for Alternative Certification (NCAC), headed by Emily Feistritzer, which keeps track of the data on alternate routes and hosts annual conferences to disseminate knowledge, practices, and policies.
concerning alternative routes through www.teach-now.org. There are also programs designed to attract specific populations to teaching, including Wendy Kopp’s Teach for America (TFA), Troops to Teachers (TTT), and the New York City Teaching Fellows Program (NYTCF). Although these “alternative” programs are sometimes characterized as being in opposition to “traditional” teacher education, they do not comprise some monolithic community, for there is a great deal of variability among them (just as there is within “traditional” teacher education) (Cochran-Smith & Zeichner, 2006; Humphrey & Wechsler, 2005; Johnson et al., 2005; Schulte & Zeichner, 2001; Wilson et al., 2001; Zeichner, 2005). In fact, under the auspices of many such programs, recruits eventually complete a relatively traditional path into teaching to gain certification. Thus, even though housed in alternative settings, so called “alternatives” can be staffed by members of the orthodoxy.

Then there is also the newly created American Board for Certification of Teaching Excellence (ABCTE)—funded by the U.S. Department of Education (which has also funded Teach for America and Troops to Teachers)—which offers its recruits an alternative “passport” into teaching. There are also smaller reforms like the Knowledge is Power Program (KIPP) schools that are frustrated with the traditional preparation of teachers and have expressed some interest in branching out into teacher preparation.

Then there are individuals and organizations that have released reports, held conferences, and raised questions about the quality of teacher preparation and the necessity of certification or accreditation. The Abell Foundation, the Pacific Research Institute, and the Progressive Policy Institute have issued reports (e.g. Izumi & Coburn, 2001). The Thomas B. Fordham Foundation (1999) issued a “manifesto” entitled The Teachers We Need and How To Get More of Them, which was signed by various critics of the teacher education establishment. The Hoover Institute has sponsored conferences; Frederick Hess (2001, 2002) from the American Enterprise Institute (an organization considered one of the leading architects of the current Bush administration’s public policies) has written reports, books, and op eds arguing that we need to “tear down the walls” of traditional teacher certification. Other critics like E. D. Hirsch (1996, 2006) and Diane Ravitch (2000) have raised questions about quality of the content of teacher preparation programs. Economists Dale Ballou and Michael Podgursky (Ballou & Podgursky, 1998, 2000a, 2000b; Podgursky, 2004) have challenged the monopolistic rationale of teacher certification and the irrelevance and intellectual shallowness of teachers’ tests. Kate Walsh of the National Council on Teacher Quality (whose advisory members include Hess, Hirsch, Kopp, among others), has written critiques of the teacher education establishment, including the recent What Education Schools Aren’t Teaching about Reading and What Elementary Teachers Aren’t Learning (Walsh et al., 2006). Recently, mathematicians and scientists concerned about teachers’ content knowledge have joined in as well. Their diagnosis, like that of the critics in the 1950s and 1960s, is that prospective teachers spend too much time in teacher education courses, thus compromising prospective teachers’ chances to learn content in university disciplinary departments. A mapping of these agents can be seen in Figure 48.2.

Boundary crossers

Some challengers take a stance in strong opposition to the orthodoxy; others, while critical, seem less radically so. The American Federation for Teachers, for example, embraces the idea of teachers as professionals, which the critics do not always do. But the AFT (1998) nonetheless has concerns about the quality of “traditional” teacher preparation, as laid out in their report, Building a Profession: strengthening Teacher Preparation and
Induction. Similarly, the Education Commission of the States (Allen, 2003), and the National Research Council (NRC), with its new teacher preparation study (as well as its study of the National Board for Professional Teaching Standards), appear to be concerned interest groups, but not clearly part of the orthodoxy or heterodoxy. Indeed, using the terms of “orthodoxy” and “heterodoxy” might communicate a static quality that is not intended. (And, of course, there is also the fact that the same person or organization can be seen as liberal, centrist, conservative, and radical by different agents in the social field at the same time.) The boundaries between the orthodoxy and heterodoxy are permeable, and groups and their alliances shift over time, as do the ideas, assumptions, and values that guide their work. Furthermore, some individuals and groups being pigeonholed: Lee Shulman (2005), for instance, champion of the professionalization agenda has also recently declared that teacher education “does not exist.” We return to this point later in our discussion.

The Education Trust, led by Katy Haycock, serves as another example of groups that blur the lines between the establishment and its challengers, as does the National Governors Association (NGA). These organizations embrace ideas that resonate with the establishment—like certification, teacher preparation, the NBPTS—while simultaneously being open to alternatives offered by challengers. The NGA, for example, embraces a range of strategies associated with the orthodoxy and the heterodoxy: “high-quality and relevant professional development activities for teachers; teacher testing and certification

![Figure 48.2 The heterodoxy.](image-url)
against high standards . . . and merit or performance pay, teacher academies, alternative routes to certification” (NGA, 2006).

This stance—embracing ideas of both traditional teacher educators and their critics—is also taken by foundations and other organizations that invest heavily in education reforms, supporting initiatives by groups and institutions from both sides of the aisle. The Carnegie Corporation of New York has provided generous support for TFA, while at the same time supporting an ambitious effort to reform teacher preparation, Teachers for a New Era (TNE), which is largely a collection of institutions within the establishment. The National Science Foundation (NSF) also supports the work of challengers and the establishment, sometimes asking oppositional groups to collaborate. The Brookings Institution, a nonpartisan think tank (although it is thought of by some as “liberal” or centrist, and by others as conservative) also takes positions that cross boundaries between the orthodoxy and heterodoxy. Arthur Levine, in his recent critique of teacher education programs intentionally took this stance, although he declared himself an insider wanting to offer a critical perspective. It may be that this category of boundary crosser also includes boundary blurrers. Together, these agents suggest a third configuration of interests groups that blurs the already-permeable boundaries between the teacher education establishment and its challengers (see Figure 48.3):

![Figure 48.3 Boundary crossers.](image_url)

In sum, the social field of teacher education is a large, shifting, crowded space with multiple communities, organizations, individuals, interest groups, and institutions. We do not offer these maps as static representations of positions, for the locations of various groups and institutions shifts over time. Nor do we want to fall into the habit—all too
Figure 48.4  The social field of teacher education.
often present in the contemporary discourse—of implying that all individuals and organizations within a group are of like mind. There is considerable disagreement within these groups; all teacher educators do not agree with one another. Nor do the challengers.

Understanding, then, that we offer this mapping as a heuristic, not as a static entity, we now turn to the content of the challengers’ critiques. We organize our comments around four major themes that run throughout challenges to the teacher education system.

THE CHALLENGES

Bourdieu (1988, 2005) argues that challengers question and redefine the value of the “products” currently “manufactured” in a field. In our case, the challengers’ critique is relatively straightforward: the current teacher education system does not “produce” high quality teachers. However, in diagnosing the root cause of the problem, four overlapping themes can be identified. Aspects of these themes have been discussed by other analysts of these debates as well, including Cochran-Smith (2006), Cochran-Smith & Fries (2001), Grossman (2004), Labaree (2004), and Zeichner (2003). Our analysis complements those.

“The cleansing winds of competition”: The problems of regulation and bureaucracy

One criticism of the teacher education establishment draws on the larger discourse of “choice.” Here critics note that, like everything else in the educational establishment, teacher education is conservative, mired in tradition, inflexible and, worse, not working. For example, Finn (2003) argues that the public education system needs to “open more gates, welcome people from many different directions to enter them, minimize the hoops and hurdles and regulatory hassles, look for talent rather than paper credentials” (p. 5). To his dismay, this is not what educators do: “The education field has developed a conventional wisdom . . . [which] boils down to: more of the same. We’re told to improve the [schools] by adding more formal training and certification requirements to those already in place” (p. 5).

Zeichner (2003) and Cochran-Smith and Fries (2001) call this general line of criticism the “deregulation” reform (the advocates call it a “common sense” reform (Hess, 2004)). Several subthemes run throughout this “market” or anti-/de-regulatory argument. First, there is the matter of unnecessary costs. The traditional system of teacher education is expensive. Prospective teachers “pay tuition, sacrifice the opportunity to work in order to attend courses, practice teach for eight to twelve weeks without compensation, and endure the red tape of obtaining additional certification if one wants to work in a state other than the one in which they trained” (Hess, 2001, p. 15). Requiring prospective teachers “to jump through . . . time-consuming but little regarded hoops,” he argues, discourages the “entrepreneurial and energetic” (p. 15).

Second is the presumed inherent positive potential of alternatives. Those who argue for an open market of teacher preparation and certification believe wholeheartedly that traditional teacher education keeps people out, especially “smart” people, career changers, and people of color. Finn (2001) claims that “this training and certification cycle is so burdensome and full of ‘Mickey Mouse’ courses and requirements that it discourages able would-be teachers from making their way into the public schools” (p. 129). If we tear down the walls, making the boundaries to the profession more permeable, we will attract better—and different—people to teaching.
Since good teachers can be found in many places, prepared in many ways, and channeled into schools via many pathways, states should scrap nearly all the hoops and hurdles that discourage good candidates from entering the classroom. Deregulating teaching in this way will not only expand the pool but also raise its quality. [p. 144] . . . The popularity of such programs as Teach for America, which places liberal arts graduates without formal education coursework in public school classrooms in poor rural communities and inner cities, indicates that the prospect of teaching without first being obliged to spend years in pedagogical study appeals to some of our brightest college graduates.

The argument here is that alternatives are inherently good, and the very existence of alternatives will attract a population “turned off” by “traditional” approaches to teacher education.

A third reason offered by the challengers for the market argument concerns a perceived lack of internal or external accountability within the social field. Critics have long noted that teacher education has been resistant to any criticism:

One of the most shocking facts about the field of education is the almost complete absence of rigorous criticism from within. Among scientists and scholars, criticism of one another’s findings is regarded as a normal and necessary part of the process of advancing knowledge. But full and frank criticism of new educational proposals rarely comes from other professional educationists.

Ten years later, Conant (1964) made a similar observation, noting that “the [education] establishment is overly defensive; it views any proposal for change as a threat . . . In short, there is too much resentment of outside criticism and too little effort for vigorous internal criticism” (p. 40).

And today’s challengers are equally concerned. As Hess (2005) notes in his meditations of the unnecessarily hostile (from every direction) discussions of teacher education, “In responding to such malicious onslaughts, the teacher preparation community does itself no favors by presuming that sharp critiques are necessarily malicious or illegitimate” (p. 197). Even when critiques are not malicious, some members of the teacher education establishment are quick to accuse challengers of less-than-noble intentions. Opening up the field to market forces would, presumably, change these tendencies. Criticism would be encouraged (not discouraged), and teacher educators would be pushed to “improve their product.”

The stridency of this deregulation and open market argument varies. Some proponents like Hess (2001, 2005) have been careful to note—unlike George Will—that opening up the market is not synonymous with closing all schools of education. Indeed, several challengers claim that there exist high quality teacher education programs. These “good” programs will, no doubt, withstand the challenges presented by a market competition. Institutions that do not offer high quality preparation will, on the other hand, fold.

In sum, the market/anti-bureaucracy argument lines up powerful ideas like deregulation, efficiency and effectiveness, free choice, accountability, and high quality (ideas that became the coin of the political and educational realm in the 1980s), and associates these ideas in a convincing, logical—for some, almost unquestionable—way to argue for the necessity of a free market approach to improve teacher education. We note also that this criticism of teacher education is tightly aligned with a similar line of argument offered
by critics of the educational system more generally (e.g. Ballou & Podgursky, 1998, 2000a, b; Finn, 2001; Hess, 2002; Hess et al., 2004). These challenges (to the larger education establishment) argue that the solution to the inherent failures of public education is privatization (through the introduction of market-based mechanisms). When an open market exists, critics argue, the rigid, constraining, suffocating divisions of bureaucracy dissolve, social structures and self-serving groups with excessive power tend to diminish, and—as a direct result—the system’s productivity and efficiency flourish since the system’s “fat” gets trimmed and money is spent in more sensible ways. Of course, these critiques are not reserved for discussions of education alone, since the market argument is part of the long, historical U.S. struggle over the distribution of wealth and power in a society that also proclaims a commitment to equity and equality.

Our goal here is to understand the heterodoxy’s complaints, and so we will not explore in detail the orthodoxy’s response, nor do we describe these challenges so as to then critique them here. That we save for future analyses; one can also see Cochran Smith (2006), Cochran-Smith and Fries (2001), and Zeichner (2003). We do briefly note, however, that in response to the market critique, the teacher education establishment often points out that public education is committed to equality; the market is not, as can be seen in the growing chasm between rich and poor in the U.S. While markets might stimulate competition, and competition might stimulate healthy innovation and change, the teacher education establishment argues that competition also stimulates sorting and selection, and might—in so doing—thwart access to knowledge and, therefore, equal opportunity, the hallmark aspiration of the U.S. public education system.

The research-base argument

A second challenge leveled at the teacher education establishment concerns the “evidence” that there is a value-added of “traditional” teacher education preparation. Cochran-Smith and Fries (2001) describe these as arguments over the “evidentiary warrant”:

Each side endeavors to construct its own warrant but also to undermine the warrant of the other by pointing out in explicit detail where methodological errors have been made, where the data reported are incorrect and incomplete, and/or where faulty logic or reasoning have led to inaccuracies and errors about the nature or size of effects.

(p. 6)

The evidence that is used to make arguments about the quality of traditional teacher preparation varies, including test scores of students intending to enroll in teacher education programs and/or licensure examination scores for graduating potential teachers. For example, in the 1980s, policymakers in New Jersey compared the licensure examination scores of alternate routes individuals and those of their traditionally prepared counterparts, showing how the latter lagged behind the former. These data were then used as an evidence to support the alternate route program (Tamir, 2006). As this debate intensified, both the orthodoxy and heterodoxy pushed for the development of better databases in order to find the best, perhaps ultimate, proof of their perspective. Science, in this case, gradually ceased to be seen as a tool to improve an objective understanding of the social reality—like some would like to believe it should—and was exploited instead as the final arbiter for decisions concerning social policy.

More recent national debates about research evidence concern the value-added of teacher education and certification (e.g. Ballou & Podgursky, 2000b; Darling-Hammond,
Darling-Hammond, 2001; and Abell Foundation (2001a, b) and Darling-Hammond (2002), as well as Darling-Hammond & Youngs (2002)). Other organizations jumped into the discussion: the U.S. Department of Education commissioned a synthesis of five questions concerning research on teacher preparation (Wilson et al., 2001). The Education Commission of the States followed up with their own report (Allen, 2003). More reports have followed, including the most recent AERA report (Cochran-Smith & Zeichner, 2005), and the National Academy of Education report edited by Darling-Hammond and Bransford (2005). A recent report from the National Council on Teacher Quality (Walsh et al., 2006)—which examines whether teacher education programs have integrated the findings of the National Reading Panel (2000) into their reading courses—offers yet another example.

Challengers’ questions about the research base for teacher preparation include: What does the research say about the qualities of an effective/accomplished teacher? Do such teachers need to have subject matter knowledge? Do they need pedagogical knowledge or other forms of professional knowledge? Do teacher education programs teach new teachers what “scientifically-based” research tells us about the teaching of reading or mathematics? Is there evidence that teachers who are certified through traditional paths are better or worse than teachers who are certified through alternative paths into teaching? Are there any observable effects of teacher education programs—holistically or in terms of program components like field experience and student teaching?

Researchers interested in these questions often employ statistical databases that attempt to align teachers according to the type of certification they hold with their students’ achievements on standardized tests, while trying to control for personal/group characteristics like socioeconomic status (SES) and race, as well as teacher characteristics like grade point averages, subject matter knowledge or major, type of university, teaching experience, and having a graduate degree in education (e.g., Darling-Hammond, 2000b; Felter, 1999; Goldhaber & Brewer, 2000; Monk, 1994). Overall, the aim of these studies has usually been to compare the teaching effectiveness (as measured by students’ test scores) of teachers who enter teaching through alternative pathways and teachers prepared in traditional programs.

Darling-Hammond and Bransford (2005) take a slightly different approach. They include research results of the sort described above, but they also ask the question: What knowledge of significant domains exists—research on learning or research on teaching, for instance? One can make a logical argument that teacher education programs ought to include such knowledge because of the nature of the work, not because a researcher found that teacher education programs that introduced such ideas produced more effective teachers (see Cochran-Smith (2006) for an elaboration of this perspective).

Even with these more generous attempts to stipulate the knowledge base of teacher education, it is fair to ask: What research-based conclusions can be drawn about the value of teacher preparation? Evidence is uneven, spotty, stronger in some domains than others. One can make a case for deep knowledge of how people learn (e.g., Bransford et al., 1999). One can make a weaker case for an established knowledge base concerning how to teach reading (NRP, 2000) or mathematics (NRC, 2001). But in general, research offers few definitive conclusions about the effects of teacher preparation or certification, field experience, subject matter and pedagogy classes, program accreditation and the like (see Allen, 2003; Cochran-Smith & Zeichner, 2005; Wilson & Floden, 2002; Wilson et al., 2001). Challengers use the lack of definitive research on the value-added of teacher education, and the uneven quality of teacher education research to support the market argument: open the gates of teacher education and certification until we have sufficient research to justify market closure. Optimistic about the effects of the open
market, they also argue that competition will speed progress in the development of better evidence.

Complicating the critiques are questions about the quality of teacher education research as well. Challengers argue that teacher educators do not, in general, conduct high quality research, use appropriate research designs, or critically appraise the research they use to support their claims. “Research that seems to support teacher certification is selectively cited, while research that does not is overlooked,” the Abell Foundation (2001a) writes:

> Analyses are padded with imprecise measures in order to conceal the lack of evidence in support of certification . . . Researchers focus on variables that are poor measures of the qualities they are interested in, sometimes ignoring variables that are better measures . . . Research that has not been subjected to peer review is treated without skepticism.

These criticisms too are part of a broader conversation about the value-added of education research. Both inside and outside of the education establishment, questions have been raised about what constitutes high quality education research more generally (e.g. Erickson, & Gutiérrez, 2002; NRC, 2002; Raudenbush, 2005; Whitehurst, 2002).

As we noted earlier, one challenge to portraying the social field of teacher education is that it is a moving target. With regard to research on teacher education, this is especially true. For example, while the research base on teacher education is considered weak by many, there are currently several important projects underway that promise to shed light on the value-added of various approaches to teacher preparation. These include the Pathways into Teaching Project (Boyd et al., 2006) and the Ohio Teacher Quality Partnership (Lasley et al., 2006), both of which are designed to compare the outcomes of different teacher preparation programs.

These discussions of warrants and “scientific” evidence very much resonate with other, larger national conversations. The uneasy commingling of science and politics can be seen in many aspects of American life. We are reminded of recent debates concerning the place of creationism in the public school science curriculum as well as arguments about the pros and cons of stem cell research. This is an old debate, for science has always been shaped by politics, religion, and power; and so it is not surprising that in the political battle for control over the teacher education field, themes of whose science, what science, and how science should be used are very much part of the discussion.

Again, we will not explore the orthodoxy’s response in any depth. We note, however, that teacher educators respond by critiquing the heterodoxy’s (sometimes) narrow view of science, most notably the claim that experimental design is a “gold standard.” They also argue that teaching is moral and ethical work, and inherently complex, and cannot therefore be adjudicated by empirical evidence alone. For some in the teacher education establishment, the “laser-like” focus on “what does the research say” can be seen as an effort to impose a totalitarian technocracy on education.

**The professionalism argument**

A third challenge concerns the “professionalism” agenda. Challenges aimed at professionalism are multiple. First, there are critics who claim that teaching is not a profession, but more like labor or civil service, especially given its unions (e.g. Mitchell & Kerchner, 1983). Other challengers suggest that teaching could be a profession, save for its failure to meet certain standards for professionalism. For example, Chubb (2001) argued that the
A professional system has two hallmarks, autonomy and accountability. Professionals are given tasks when the requirements of doing them well dictate the exercise of ample discretion. The freedom to exercise discretion—autonomy—is then checked by the system with provisions for accountability. These provisions generally focus on the results of the tasks, not on how the tasks themselves are carried out. A professional model of education would recognize that teachers and schools need to decide how best to educate each student. The system would not monitor or particularly care how each school provided education; the system would care about and monitor what students learn.

So the challenge here is not that teaching ought not be considered a profession, but that it remains more a pseudo- or quasi-profession. A similar challenge concerns the lack of agreement concerning professional knowledge. Again, critics point out that a hallmark of professions is a shared, specialized knowledge base. Challengers note that teaching does not have the agreed-upon body of professional knowledge and skill that the professions of medicine and law have:

The problem is that no comparable body of knowledge and skills exists in teaching. Debate rages over the merits of various pedagogical strategies, and even teacher educators and certification proponents have a hard time defining a clear set of concrete skills that makes for a good teacher.

While not critics, both Cusick (1992) and Labaree (2004) make similar points about the “soft” technical core of teaching. Within this critique, challengers are impatient with the teacher education establishment’s inability or unwillingness to describe teacher knowledge and skill in concrete terms. Vague language is used to describe good teaching: Good teachers “reflect” and “listen,” they take “global perspectives,” they “model.” This “educationese” frustrates critics who want to know what these terms mean, and how they can be measured. They want a better articulation of the “technology” of good teaching, as perhaps best illustrated by the report of the National Reading Panel (National Institute of Child Health and Human Development, 2000). Furthermore, challengers ask for evidence that the knowledge and behavior valued by the establishment is positively correlated with student learning (Hess, 2001). If the orthodoxy cannot or will not explicitly and clearly lay out measurable standards for what teachers need to know, the challengers suggest, “we ought not keep people out.... This is not to say that we think incompetence is acceptable in such a profession—only that we recognize licensing as ineffective and potentially pernicious way to control quality” (p. 11).

Much of the discussion about teacher knowledge focuses on issues of teacher content knowledge, largely because everyone—members of both the orthodoxy and heterodoxy—agrees that teachers need to know something about the subject matters they will teach. But discussions about teachers’ content knowledge (its content and character, adequacy, balance with other forms of professional knowledge) are equally fraught. This may be because some challengers implicitly or explicitly claim or are misunderstood to be claiming that content knowledge (and verbal ability) are really all that matters in teaching, either because there is no professional knowledge base or because teaching is a
practical art, one best learned through and in practice, not in professional schools (e.g. Whitehurst, 2002). The fact that many teachers—especially elementary teachers (e.g. Ball et al., 1990; Ball et al., 2001; Ma, 1999) and misassigned secondary teachers (e.g. Ingersoll, 1996)—do not have adequate content knowledge leads some challengers to accuse teacher educators of spending too much time on education courses and not enough time enhancing the liberal and disciplinary education of future teachers. Teacher licensure tests only serve to reinforce this sense of low standards for teacher content knowledge. In one study, for example, Mitchell and Barth (1999) found that most of the tests were multiple choice, aimed at high school level knowledge. “We found no evidence of content [knowledge] at the baccalaureate level” (p. 8).

In sum, there exists a deep suspicion among critics that there is no articulated, measurable knowledge base for teaching, and that the teacher education establishment wants the entitlements due professionals, but not the obligations.

The stridency of these challenges vary, with some critics admitting that teaching might be a profession, but that it still has important work to do to meet the minimum requirements of a profession (e.g. an agreed upon professional knowledge base, internal accountability), and others claiming that teachers need verbal ability and some content knowledge, nothing more, nothing less. Even critics who argue that teaching is a profession and that teachers do need professional knowledge nonetheless challenge the orthodoxy for the mediocre content preparation of teachers, as well as the lack of rigorous licensing examinations (see Crowe (this volume) for further elucidation on these issues).

Social justice: the “ideology” argument

Many education schools discourage, even disqualify, prospective teachers who lack the correct “disposition,” meaning those who do not embrace today’s “progressive” political catechism. Karen Siegfried had a 3.75 grade-point average at the University of Alaska Fairbanks, but after voicing conservative views, she was told by her education professors that she lacked the “professional dispositions” teachers need. She is now studying to be an aviation technician. (Will, 2006)

The final challenge involves the accusation that the educational establishment is held hostage by a suffocating ideology that—despite its protestations to be liberal—does not welcome alternative perspectives. Hirsch (1996) writes of an “orthodoxy masquerading as reform” and “totalitarian intellectual dominion”; Finn and Ravitch (1996) have accused the education establishment of a “pedagogical correctness” (p. 41). Let us begin by considering what challengers perceive as this ideology.

The teacher education establishment long ago embraced a progressive stance toward K-12 education (Dewey, 1902; Hirsch, 1996; Ravitch, 2000), and one subtheme of the “ideology challenge” concerns the perceived effects of progressivism on the quality of the curriculum and what students learn. Ravitch (2000) argues that the teacher education establishment’s progressivism led to “unrelenting attacks on the academic mission of the schools,” which—she argues—account for why so many children are “left back”: “Such [progressive] policies, packaged in rhetoric about democracy and ‘meeting the needs of the individual child,’ encouraged racial and social stratification in American schools” (p. 15).

Hirsch (1996) makes a similar argument, but avoids the language of “ideology” because he sees the educational establishment as taken over by a set of ideas (rather than a single “ideology”). Instead, he asserts that the education establishment exists within a
“thoughtworld,” composed of three “intellectual impulses”—Romanticism, American exceptionalism, and professionalism—all of which are problematic when applied to educating children:

The psychological and ethical assumptions of Romanticism have not worked out the way their originators had hoped and predicted. Romanticism may have created some of the greatest poetry in our language, but its theories of education have been wrong theories. American exceptionalism does have some basis in reality in that our democratic political traditions and our habits of intellectual independence are special in world history; but exceptionalism can become mere complacency that evades the challenges of learning from the experiences of other peoples. Professionalism in the noblest sense denotes both heightened pride in one’s work and a heightened sense of responsibility; but extreme professionalism becomes narrow and separatist.

It is important to note that both Ravitch’s and Hirsch’s condemnation of the progressive ideology is rooted in their firm belief that these ideas have worked against the “social justice” agenda that many members of the teacher education establishment hold dear. Their critique, in other words, is not of the orthodoxy’s commitment to equal, high quality education for all. Rather, it is a critique of the strategies that the educational establishment has used to achieve that equality. For critics of the establishment, progressivism is not synonymous with equitable education.

In addition to its failure to make good on its commitment to high quality education for all children, some challengers feel as if the orthodoxy is attempting to impose a Romantic, Progressive, constructivist values on everyone. Hess (2005) explains:

[Many critics are concerned that leading voices in teacher preparation ... have unapologetically argued that teacher education is inescapably about championing certain values. ... Ladson-Billings, current AERA president, has said that her personal vision of good teaching is promoting an “anti-racist, anti-sexist, anti-homophobic ... Anti-oppressive social justice pedagogy,” despite her acknowledgement that such teaching will inevitably entail “unpopular and politically dangerous” curriculum and pedagogical decisions.

Why is this dangerous? Because many teachers, Hess (2001) argues, are young and impressionable, and because the teacher education establishment’s values do not reflect those of the larger society:

By entrusting schools of education with control over entry into teaching, certification lends the instructors a privileged position in sensitive social and moral discussions. This would be of little concern if education faculty mirrored the divisions with the larger society, but this is not the case. Professors of education tend to espouse a “constructivist” conception of pedagogy, curriculum, and schooling. It is received wisdom in teacher education that aggressive multiculturalism is a good thing, that aspiring white teachers ought to be forced to confront society’s ingrained racism.

Recently, challengers have focused their critiques on the increasing emphasis on “dispositions” in teacher education and program accreditation. Anecdotes abound about prospective teachers who are removed from teacher education programs because they reject the progressive ideas of constructivism, oppression, and social justice. Damon
(2005) observes that NCATE’s standards “imply that a successful candidate must demonstrate the right kind of beliefs and attitudes” (p. 2) in terms of “dispositions” like caring and social justice. What is more, the NCATE standards suggest that teacher candidates must not only have such beliefs, but their actions must be guided by them. What concerns Damon is that NCATE’s use of the language of “disposition” does not reflect knowledge of the work of social scientists on dispositional traits, which emphasize behavioral tendencies, not moral values or socio/political ideologies. This is problematic:

Those who have been given the authority to assess teaching candidates have been given unbounded power over what candidates may think and do, what they may believe and value, and those who are subject to this authority (the candidates) must guard their every expression of moral belief and commitment.

(Damon, 2005)

So, do the challengers want U.S. schoolteachers to ignore racism or to be sexists? Do challengers think that teachers should treat children or their parents differently depending on their gender, race, class, or sexual orientation? Perhaps some do. But it is overly simplistic to presume that challengers are racists who want to maintain the status quo. Essentializing this critique obscures the complexity within. Our country is deeply divided over issues of gay marriage, welfare, religion. Teachers are, in many ways, caught in the middle, for as public employees they must respect and work across those differences. However, the discourse proclaims that teachers have to have one set of values (anti-sexist, anti-racist, etc.); the very act of marginalizing those who have different values is, paradoxically, illiberal. Or, as Finn and Ravitch (1996) once noted, “the pedagogical tent, as it turns out, is not very big at all” (p. 41). While we cannot explore this complexity in all of its depth here, we offer a few observations.

Arguments about teacher education are predicated on assumptions about what teachers should do in schools and who they are. Assumptions about teachers are predicated on assumptions about the purposes of schools. Americans do not agree on this fundamental issue. There are those who see schools as the place where we hand down to children the heritage of our glorious past and present; for others, who are (often) more skeptical of U.S. claims to greatness, schools are places where teachers work as change agents, preparing students to reinvent the world, to radically overhaul society’s inequities, and to reimagine our country. Further, we do not only disagree on our assumptions about schooling, we differ on a range of other values as well; one sees the on-going battle for whose social values will triumph in debates about social security and health care, in stem cell research and intelligent design.

When some challengers critique the “social justice” agenda of the teacher education orthodoxy, they are reacting to what they see as a homogeneity among teacher educators and their radical social vision. Challengers experience this homogeneity as a form of “Orwellian mind control” which first captures and brainwashes the young minds of prospective teachers, and later—through them—threatens to control the minds of children. Those prospective teachers who dare to resist—according to the challengers—are aggressively condemned, stigmatized, and denied the opportunity to become teachers.

This challenge raises two philosophical issues; the first concerns cultural relativism, the second touches on the controversy between the rights of professionals to promote a normative value system through their practice that might stand in contrast to the common normative perspective of the layman. There are no easy answers to the dilemmas raised by these issues, and those who raise them cannot be dismissed as simply conservative, racist, and xenophobic (even though there are among the challengers a range of such
views). This critique, if taken seriously, suggests that some groups feel like their core value system is violated and disregarded by the orthodoxy’s agenda. Ironically, as critics will point out, this oppression of difference in viewpoint goes directly against the commitment to multiculturalism and diversity that the teacher education establishment seeks to nurture when it comes to other groups like minorities, immigrants, and other oft-times marginalized populations.

The Progressive ideas seem even more dangerous and oppressive to the critics, since they enter the discourse through the agenda of professionals who use their professional power to make their ideas and knowledge look authoritative, objective, and “true.” In the case of education—where knowledge and truth are so seriously contested—challengers see this as an irresponsible and undemocratic misuse of power by a liberal minority who tries to impose their ideas on the entire society.

Again, the challengers vary in their stridency. Damon (2005) explicitly notes that it is not clear whether the decision to write the NCATE standards in this way was simply sloppy scholarship or an “intentional dictatorial effort at mind and behavior control” (p. 5). Other challengers—like the positions articulated by Will (2006) and Hess (2006)—are quicker to draw conclusions that the teacher education establishment is intentionally enacting an “Orwellian mind control” (Damon, 2005).

These discussions have undertones of our larger national discussions about “moral values.” While at times, challengers say that they are mainly concerned with the “imbalance” of views and values that are reflected in the teacher preparation curriculum, at other times, the critiques sound more like accusations that the progressives (like the larger liberal Democratic Party) lost their moral compass, and that schools—and teacher education establishment more specifically—need to return to “moral”—it is unclear whether this means “Christian”—values. It is not surprising, then, that one theme in challenges to the orthodoxy concerns the predominant values of that community, including Progressivism, constructivism, Romanticism, social justice, equal opportunity, equality, and equity.

RE-VISIONING THE TEACHER EDUCATION ESTABLISHMENT

Our goal in the chapter was modest: to examine the usefulness of Bourdieu’s ideas about social fields to help us understand the current jurisdictional challenges to teacher preparation and certification, focusing on the criticisms to the establishment, not the orthodoxy’s responses to those challenges. While some might dismiss the ideas of orthodoxy and heterodoxy out of hand, for us, the Bourdieuan frame is helpful. We are persuaded that there is an orthodoxy, albeit loosely coupled and constantly shifting, and that the social field of teacher education is characterized by a dominant set of norms, values, ideas, ideologies, and assumptions that shape the ways that social agents operate. Bourdieu would call this socialized behavior of agents their “habitus.” Put simply, habitus is the set of dispositions, behaviors, beliefs, and norms that one acquires through life. These are affected by one’s sources of capital—economic, cultural, and social—and the position one occupies in the social field. The habitus conditions the way social agents understand the field, or as Bourdieu put it, the habitus is the agent’s “feel for the game.” According to Bourdieu, then, our rationality is bound and defined by the sources of capital we possess, our habitus, and the position we occupy in the social field(s).

Based on this theory, we argue that although the teacher education establishment is relatively remote from some of the heterodoxy’s agents and thus often resistant and dismissive to their ideas, the teacher education establishment would benefit from under-
standing with more acuity the structure of our field, the types of agents that operate in it, and the positions that these agents currently occupy. The problem with one’s habitus is that one is often not aware of it; norms and values are implicit and tacitly accepted. Thus critics play an invaluable role by helping us “see” our norms and assumptions through their challenges. Indeed, we have found stepping back and examining the critiques very helpful in examining our own assumptions and world views. (We rely here on the old anthropological premise that understanding the other helps us better understand ourselves.) We conclude by first summarizing how the challengers perceive the orthodoxy and then reflecting on the major criticisms to the teacher education field.9

So what do the challengers “see” when they experience the teacher education establishment? (And remember, the teacher education establishment includes the 1,300+ teacher education programs that currently exist.) They see a set of omnipresent ideas—ideas that are, at times, experienced as oppressive and stifling, despite their liberatory intent. Those ideas include Progressivism—with its hallmark belief that the purpose of government is the good of the people as exemplified in the work of Jane Addams and Hull-House (Bentham, 1879; Himmelfarb, 1991). More specifically, they also see progressive education ideology, with its attention to the child and experience; its “naturalistic” and Romantic ideas about learning; its hands-on, project-oriented pedagogy; and its skepticism about authority (teachers are, after all, not lecturers but guides, facilitators, and collaborators). Critics also see, at best, ignorance of, and at worst, an active resistance to ideas antithetical to or different from their own progressive notions, including empirical evidence about the “science” of learning and teaching. Challengers also see a commitment to a particular version of social justice, one that argues that all teachers should have certain values, beliefs, and dispositions, including a commitment to becoming change agents, to remedying inequalities in society, and to giving each and every child access to future economic, intellectual, professional, and personal success. They also see a rhetoric of teachers-as-professionals without the attendant obligations that accompany that status. And they see a bureaucracy—swollen, slow, conservative.

Equally important is considering what some of the challengers fail to see. Many among them do not see a field where teachers leaving preparation programs are highly qualified. Many do not see teachers with impressive—or even sufficient—content knowledge. Many do not see teacher educators critiquing or closing down preparation programs that are mediocre. Many do not see innovation or responsiveness. Many do not see the critique of progressivism or skepticism about particular progressive pedagogies. Many do not see some hallmarks of professions: internal accountability, an agreed upon knowledge base, specialized and rigorous training, challenging licensure examinations. Many do not see agreement about what the content of teacher education programs should be, nor do many see evidence that the field keeps up with current research-based knowledge about effective teaching.

So what? For one, Bourdieu helps us understand that, whether we would like it or not, the borders between the orthodoxy and heterodoxy are permeable, ever shifting. According to Bourdieu (2005), the struggle for domination in the field is constant, and continues as long as the field can provide space for challengers to operate and manifest their ideas. In this process, agents who were disenfranchised in the past are the potential challengers looking for opportunity to take control over the field in the future. Indeed, the social field of teacher education looks very different than it did 20 years ago. A case in point: The 500+ alternative routes into teaching, which currently exist in 48 states and the District of Columbia. Alternative routes are now part of the establishment, as is Teach For America, Troops to Teachers, and the like. Accountability and standards that were seen by many in the establishment as inappropriate ideas that impose a business mindset on
the field are now part of the education landscape. So are more than ever before ideas of merit pay, which can be seen on the agendas of the NBPTS and the ABCTE.

As Bourdieu (2005) claimed, outsiders can change, (sometimes) dramatically, the way fields operate. Domination of certain groups depends on the value of the different sources of capital they possess—economic, social, cultural, bureaucratic. When the value of a capital (its “rate of exchange”) deteriorates, the authority that was based on it is questioned too. This means that other agents who bring with them new ideas—based on other sorts or combinations of capital—are able to gain more authority. So, for instance, alternative routes became a legitimate part of the structure of power in the field of teacher education when they were able to successfully question the structure of capital that supported and justified the “old” teacher preparation system run by the orthodoxy. Instead of the cultural capital of teacher educators that praised the importance of progressive pedagogy, the serious alternate routes suggest an alternative which argues for the importance of broad liberal art education and disciplinary specific content background for teachers. And with very little research to rely on—either research that explicates the professional knowledge base of teaching/teacher education or research that demonstrates the value-added of teacher education—the orthodoxy’s capital further erodes.

So how do we—as members of the “old” orthodoxy—respond, especially as the value of our capital shifts? Not, we contend, by dismissing all criticism out of hand as wrong-headed, anti-democratic, conservative, or oppressive. Nor is it helpful to politely accept all criticism on face value. Certainly, all critics and criticisms are not equally worthy of serious engagement, but many are. And their criticism might help us see what forms of capital we need to develop. While Bourdieu argues that economic capital will trump all other forms of capital, he also noted the power of cultural capital.

If the traditional cultural capital of the teacher education establishment has eroded, what new forms of capital might we acquire? Perhaps it is time to agree upon a knowledge base that all teachers should acquire in teacher preparation programs. A common knowledge base has not thwarted the commitments of medical or law or architecture schools to tailor their professional programs to particular foci; it should be possible for us to have a national collective commitment while also leaving room for programs to have particular strengths. The development of such a knowledge base would also require a commitment to sound educational research that produces both publicly credible and professional responsible results. If we had a collective answer to the question, “What do teachers need to know and be able to do?” and we had some evidence of the effects of that teacher knowledge on students’ learning and development, then it would not be as easy for our challengers to take over aspects of our work (teacher preparation or licensure). Such cultural capital would lead to other forms of capital, including more control over the bureaucracy.

But building up more cultural capital is not sufficient. We might also need to become much more open to internal and external critique, for democracies and vital institutions depend on dialectical tension. To the extent that there is even a kernel of truth in the image of the teacher education establishment reflected back to us by our challengers, we have some serious work to do.

But the dialogue we suggest is by no means an invitation for challengers to take over the positions of power in the field, nor is such a dialogue our idea alone (the voices of insiders and outsiders in this volume is testimony to that). Conserving the relative autonomy of the field of teacher education from the grasp of other fields (like the state bureaucracy, business corporations, and religions) is essential for the future of public education, for teacher preparation needs to be protected from control by a singular ideology (including from within). Thus, while autonomy does not necessarily mean conserving the old
order, it definitely does not mean caving to the narrow interests and ideology of the
economic elite whose interests are powerful and invasive. We cannot disregard the fact
that some of the challengers’ arguments were cultivated in conservative think tanks
funded by these interests; there might be those among the challengers whose interest is
solely in the demolition of the politically powerful teachers’ unions (and they see teacher
education as the softest spot in the system). Indeed, Bourdieu noted the tendency of
economic elites to use their economic capital to establish their interests in a seemingly
legitimate acceptable order that can supposedly be profitable to everybody. But we know
that the open market does not lead to a more equitable society; the gap between the rich
and the poor of this country only continues to yaw.

We also know that the challenges and the challengers are not a monolithic bloc. The
jurisdictional challenges to teacher education of the last 20 years is not a simple story of a
battle between the narrow ideas of an economic, conservative, sometime religious elite
and the democratic, progressive, liberal teacher education establishment. We believe that
the reality is much more complex. Some challenges do not represent the interests of
economic elites, but rather the interests of other groups that have been systematically
excluded from the discourse by the orthodoxy, because their ideas are simply different.
Examples for these kinds of groups are the ABCTE in the area of certification; TEAC
in the area of accreditation; and Teach for America in teacher preparation. Each of
these organizations has been battered by some representatives of the teacher education
orthodoxy who out-of-hand have dismissed the value of such alternatives. But if we care
about democracy, these organizations (and others) should be allowed to participate in
the conversation about how best to prepare high quality teachers. Disregarding and
alienating these groups is far more dangerous, as other challengers who do represent
narrow undemocratic interests can argue that the current system is authoritarian and
undemocratic and thus should be replaced altogether. Indeed, all professions carry the
burden of being self-serving, monopolistic, and exclusionary. They talk about their
mission to serve society, while focusing on fortifying their privileges.

Neo-Weberians argue that professionals tend to monopolize their work environment
and its associated benefits, thus increasing social inequality. This criticism is based on a
conflict perspective that views the social reality as a place where individuals and groups
struggle to gain control over various kinds of resources (Weber, 1952). Among and
within professions, then, there is a constant tension between “insiders” (the professionals
who wants to act as gatekeepers and restrict access to prevent oversupply) and “outsiders” (those who cannot overcome the obstacles put by professionals and therefore are
denied of the benefits associated with membership). Collins (1990) argues that “instead
of merely responding to market dynamics . . . occupations attempt to control market
conditions. Those which are especially successful are the ones which we have come to
call the professions” (p. 25). Professions look to secure and preserve their privileges from
the instability of the labor market and possible competition of other professions by
surrounding their work with social rituals and turning their everyday practice into one
that generates sacred symbols (Abbott, 1988; Collins, 1990). Education and credentials
are among the social rituals that establish public legitimacy, which—in turn—enables
professionals to follow practices of market closure and exclusion of non-members
(Collins, 1990; also see Tamir & Wilson, 2005).

These two contradicting approaches emphasize the ambivalent/ambiguous nature of
professions, which might serve public interests, but at the same time might attempt to
better its members. Pels (1995) conceptualizes it as a “Janus face”: the concept of profes-
sional autonomy “came to display an intrinsic duplicity or duality in which good and evil,
functional necessity and dysfunctional domination, appeared to conspire closely” (p. 81).
While there is reason to believe that, on some occasions, the public is better served by a professional entity rather than being solely exposed to the political and economic interests of state administration and business community, professionals—at the same time—must protect that public from the dangers of the profession’s power and monopoly.

Can research help us here? Research and science will never be objective or disinterested. They are, by definition, part of the field that they seek to study. And the politics of the field have deep effects on the subject of study, the research questions, the method and design, and presentation of the outcomes. All the while, it would be unfair to stigmatize all research as an advocacy work. There is work that is productive and illuminating in the sense that researchers aim to promote and advance the field as a whole irrespectively of its current political structure. We do believe that work like the scholarship represented in this handbook, which is designed to help the members of our field think and act responsively and critically, in ways that might help foster a more open climate to diverse ideas (while keeping and developing a professional autonomous core that aims to serve the public good in a comprehensive and democratic way) is potentially contributive to the public. We believe that other scholarship—of different genres and about different questions—can also help, if done with methodological acuity and moral grace.

In the end, in our continuing efforts to build a teacher education system that prepares and nurtures well-prepared teachers, we must engage other groups in our discussion. This does not mean that we should strive for a false unity or a consensus, for these are unrealistic, paralyzing, and sometimes undemocratic practices. Every field needs some diversity of ideas and an active heterodoxy in order to stay vibrant, productive, and in the case of a “professional” field, a real servant of the public good. Moreover, as Bourdieu and Wacquant (1992) have argued, the whole notion of a social field rests on the premise of a struggle between social agents (when there is no heterodoxy, the field simply ceases to exist as a field). Nevertheless, the price to pay for more openness on the part of the current orthodoxy is not insignificant. Diversity and openness to other ideas and approaches means navigating more persistent and impassioned political dynamics and less likelihood of the old elite preserving and perpetuating its positions of power and ideas. On the other hand, the field as a whole can benefit from a more democratic struggle that would surely act first, as a fodder and catalyst of needed change, and second as a mechanism to garner more public legitimacy for the field. This kind of evolution might better position members of the ever-evolving teacher education orthodoxy in the social space, as a professional field that might become a better servant of the public good, enjoy more legitimacy, while significantly reducing its self-serving practices, the immanent ills of any and all professions. In the end, the social field of teacher education will only thrive to the extent that we embrace these challenges, sort through them carefully, and respond to those that will help us prepare better teachers for America’s children.

NOTES

1 For one analysis of these arguments, see Cochran-Smith (2005) and Cochran-Smith and Fries (2001), as well as the entire issue of the Journal of Teacher Education devoted to the politics of teacher education (volume 56, number 3). Cochran-Smith and Fries (2001) assert that the critics are more inappropriate in their criticism; we are not as sanguine about this.

2 This phenomenon is common in the “culture wars,” especially those concerning curriculum. For instance, political liberals who align with educationally conservative ideas (e.g. teach the “canon”) are often misrepresented as political conservatives (Wilson, 2003). This can be frustrating for critics, and lead to further alienation from the teacher education establishment.

3 We are aware of the problematic nature of the use of terms like “objective” or “balanced,” but
we believe that it is both possible and helpful to attend to multiple perspectives simultaneously all the while acknowledging that no perspective is purely objective.

4 We do not use the language of “establishment” in a derogatory way as sometimes is presumed given its connotation. But we do use it to capture the perspectives of critics who experience and interpret the sometimes loosely coupled system that supports traditional teacher preparation as a unified bloc, as articulated by Conant (1964). Conant and others also used the language of “educationists.”

5 In drawing these maps, we draw both on the work of Bourdieu and that of Spring (1997). We do not aim here for a comprehensive map of all agents and associations. Indeed, such a map would be very difficult to read. However, we hope here to evoke some sense of the complexities of the social field of teacher education. A further complication is that the teacher education establishment is embedded in the larger education establishment, full of even more agents and relations. Similarly, while this picture focuses on the national landscape, there are state level and local associations and actors as well (where Murray (this volume) argues that most of the action actually takes place), and the considerable variation across states and localities is also not captured here.

6 Throughout the essay, we use teacher education “establishment,” “system,” or “orthodoxy” as shorthand for the loosely coupled set of individuals and organizations portrayed in Figure 48.1.

7 The questions that the challengers do not ask are equally important to the establishment. For instance, critics have not asked: To what extent do teacher education programs prepare teachers to teach diverse student populations and students with disabilities? This kind of question is very important to members of the teacher education establishment, and reviews of relevant research can be found in Cochran-Smith and Zeichner (2005) and Darling-Hammond and Bransford (2005).

8 Zeichner (2003) argues that there are three approaches to recruiting teachers: professionalism, deregulation, and social justice. These approaches roughly parallel three themes of the critiques we describe here. However, Zeichner folds the argument that teachers need nothing more than content knowledge into the deregulation critique. We prefer a different conceptualization since not all de-regulators argue that there is no professional knowledge save for content knowledge.

9 We note also as Merleau-Ponty’s (1945/1962) explains in Phenomenology of Perception, meaning is derived from understanding our own and others’ perceptions. Perceptions can be true or false; that is of no matter, for understanding from a phenomenological point of view is dependent on understanding people’s objective experiences and interpretations of the world. Here we are not arguing that the challengers’ perceptions are “true,” only that they are important perceptions for us to seriously consider, for our social field changes, due in no small part to these forces.

DIVISION OF FRACTIONS

1 How do you proceed when either of the fractions is a mixed number or a compound fraction?

2 Divide \( \frac{3}{4} \) by \( \frac{2}{5} \) and give clearly the rule and reason.

3 What is the sum and difference of \( \frac{49}{16} \) and \( -\frac{34}{5} \)?

4 A man being asked how many sheep he had, said he had them in three fields; in the first he had 63, which was \( \frac{7}{8} \) of what he had in the second, and that \( \frac{5}{3} \) of what he had in the second was just 4 times what he had in the third. How many sheep had he in all?

DUODECIMALS

1 If one inch be divided into 12 equal parts, what is each part called?

2 Give rule and reason for multiplication and division of duo-decimals.

DECIMAL FRACTIONS

1 How does the value change from the left toward the right?

THEORY AND PRACTICE

1 How would you organize a school?

2 What spirit should one possess who has access to the sanctuary of the mind?

3 What motive should govern the teacher, moral or pecuniary?

4 What especial preparation does he need who is to play upon the “harp whose tones, whose living tones, are left forever in the strings?”

5 What can you say of the responsibility of the teacher?

6 What can you say of the ventilation of the school-room?

7 What should be the appearance of the school-room?

8 What can you say of the teacher’s responsibility for the health of a child?

9 Would a knowledge of Mental Philosophy be a valuable acquisition for a teacher? Why?

10 Should a teacher be held responsible for the intellectual growth of his pupil?

11 Describe the ORDER OF STUDIES to be pursued by the pupil.

12 Should the teacher be responsible for the moral and religious training of his pupil?

7.2 Training of teachers

W. C. Bagley
Teachers College, Columbia University, New York

Source: W. C. Bagley, Training of teachers. Proceedings of the National Education Association, USA, 1919, pp. 499–504

American policies regarding the professional preparation of teachers have pretty faithfully reflected the attitude of the public toward teaching as a career. It is unnecessary in this audience to rehearse the facts regarding our backwardness in this, the most important function of a democracy. We all know that our normal schools, generally speaking, are more penuriously supported than any other institutions of similar grade or approximate significance and responsibility. We know that they do not hold a place in the public esteem that is comparable to that of the colleges of liberal arts, engineering, agriculture, medicine, or law. We know that they suffer in consequence, both in the advantages that they are able to offer and in their attractiveness to ambitious youth.

All this is clear enough to us, but for some reason it is not clear to the public. There are certain fundamental facts that deserve to be reiterated until their deep significance has sunk home. There are four upon which I should lay particular emphasis.

In the first place the high-school graduates now entering the normal schools to prepare for public-school service represent a significantly lower level of mental ability than do the high-school graduates who are looking toward other professions. This fact is definitely suggested by investigations that have been undertaken in one large and typical state; that the same condition obtains in many if not most of the other states is vouchsafed for by the testimony of those long familiar with the situation. Not only are the great masses of public-school teachers relatively short-lived in the service—half of all teachers remaining in the schools but four years or less, and fully one-fourth of all leaving at or before the close of the second year—not only are the majority of these teachers without professional training, but even the relatively few who are now preparing with any degree of seriousness for the work do not represent, as a group, the very best available material. There is no doubt that this condition has developed chiefly within the past ten or fifteen years, and that the normal schools before that time were selective of a relatively better grade of student; but with the ever increasing opportunities for women to enter other callings, the situation in the public-school service is certain to become more and more serious unless immediate steps are taken to make classroom teaching a permanent, attractive, honored, and well-rewarded profession.

Another fact of which the public should become thoroughly aware is the low rank that we hold among the civilized nations with respect to the preparation of our public-school teachers. Just before the war began, for example, two-thirds of the elementary teachers in England were professionally prepared for their responsible work. I mean by this that these teachers had had a preparation that would be equivalent in this country to graduation from a four-year high school plus two years of normal-school training. In the United States not more than one-fifth of the elementary teachers have had so extended a preparation.

Now is our standing low only in comparison with countries like England and France. One of our South America sister-republics, Chile, supports sixteen normal schools for a population of 4,000,000—five more than Massachusetts operates for a population about equal to that of Chile. While these Chilean normal schools do not require our equivalent of high-school graduation
for admission, they keep their students in residence for six years and provide for them not only tuition but board, lodging, and clothing during this long period of professional study and training. Today 40 percent of the teachers in the elementary schools of Chile are graduates of these extended professional curricula, and the remaining 60 percent have had some professional preparation.

It is clear that if our people wish to continue their leadership in a democratic world they must be awakened to the significance of this most important democratic function of providing competent teachers for the children of the nation. Practically every other civilized country has adopted for the education of its public-school teachers the same liberal policy that we have adopted for the training of our officers for the army and the navy; that is, the selection of candidates upon a rigorous basis of merit and the careful education of these candidates at public expense. In the United States as in other countries the overwhelming majority of the public-school teachers are recruited from families that are unable at their own expense to send their children to normal schools for extended periods of professional preparation. There are two ways out of the difficulty. One is to require adequate professional preparation and limit certification to those individuals who can afford to secure this preparation. The other is to require professional preparation and then keep the profession open to all qualified candidates by providing the training at public expense. Our people have adopted neither method. They have kept the standards of certification so low that candidates readily secure licenses without any preparation worthy of the name, and they have established normal schools with the expectation that students will enroll voluntarily in large numbers for the privilege of securing training at their own expense and then competing with those who have been permitted to enter the profession by the back door. The result is one that could easily be predicted. Not only do the normal schools, as we have seen, fail to attract the best available talent, but they graduate less than one-sixth of the number of recruits needed each year to fill the vacancies in the elementary schools alone. Most of the graduates go into those city systems that are progressive enough to demand some measure of professional preparation, leaving to immature and untrained recruits the rural and village schools, in which more than one-half of the nation’s children receive all of their schooling.

A third fact that should be brought before our people is that the kind of education that they expect the public schools to provide for their children can never be provided unless the standards for the preparation of teachers are raised far beyond what they are today even in our most progressive city school systems. Of course not all of the miracles that some people expect from the public schools can ever be brought about, any more than anyone can ever square the circle, or construct a cube that will be double the contents of a given cube, or devise a machine for perpetual motion. The sooner we recognize some of these impossibilities the better it will be for our cause, for good school men and even professors of education sometimes lose their heads over beautiful dreams that could be realized only if we were able to go back to the beginnings of things and reconstruct the human race on a different pattern. But even modest and eminently sane hopes of educational betterment must await a general level of teaching skill and teaching insight now to be found only in the rarest cases. Many parents who have a vague but sincere conviction that their children are not getting what they should from the schools are not expecting miracles, but they are expecting goods that cannot be delivered by a teacher whose equipment comprises at most a four-year high-school education, with a little professional training which has attempted in one or two years to prepare her to teach every subject and supervise every activity in an eight-year educational program.

A fourth fact deserves especially serious consideration. Our neglect of adequate preparation for teachers has led to the creation of a system which was designed to compensate for this neglect, but which in itself bears the seeds of very great evils. I mean frankly the effort to compensate for poor preparation thru elaborate systems of supervision. This is rapidly bringing into being a group of superteachers, if I may use the term, better trained and much better paid
than the classroom teachers and bearing to the latter a relation akin to that of the foreman of a factory to the "hands" of the factory. More and more the plans and specifications for teaching are being prepared by these superteachers. While they have been selected in the past very largely upon the basis of their success in doing actual first-hand teaching, this condition is rapidly passing, and in any case their work means a detachment from the real first-hand problems of teaching and managing boys and girls. The classroom teacher, instead of looking upon his work as a fine art, is forced to look upon it as a mechanical trade; instead of being the artist that he should be, the present tendency is forcing him more and more insistently into the position of the artisan.

Now if a painter achieves success he does not forthwith surrender his pigments and his palette to a group of amateurs and expect them to paint great pictures under his direction. Nor does the successful actor retire permanently to the wings, with the expectation that the stage hands and the scene shifters can, even under his direction, read his lines to crowded houses. Nor does the successful novelist hire a group of hacks to put together his next great book. But if the great artist still agonizes over his first-hand materials, if the successful actor, not in spite of, but because of, the transcendent fame that he has won, still acts before the footlights, if the novelist still constructs his own plots and delineates his own characters, it is because they know that each added increment of success brings its corresponding reward and recognition. Until in the work of education we can insure that the teacher can profitably capitalize his success and still remain in first-hand contact with the materials of his art, teaching will remain the sorriest of the trades.

It may be too late to correct in industry the evils that the factory system has brought about. It is not too late in education. The problem is immediately to place teaching in the only position in which it can hope to render its all-important service—to give the actual work of first-hand teaching its true status as a fine art. This means above all a vast extension of our agencies for the initial preparation of teachers. This will solve the problem, and nothing else will.

I am convinced that it is the most shortsighted of policies to attempt to prepare a teacher in two years to fit successfully into any grade that happens to have a vacancy when she seeks appointment. What the child of eight or nine or ten years needs in the way of teaching is not what the beginner needs or what the eighth-grade pupil needs. The teaching difficulties that are involved in only a circumscribed range of school work are enormous when one comes to catalog them. The demands upon even a fourth-grade teacher who would do well the work of that grade are as severe and as exacting as any individual should be expected to bear. Until we dispel the fatuous delusion that the equipment of the teacher must vary directly as the age of the pupil, we shall never have in the elementary school the level of expert service that we must have if these basic schools are to do their basic work. If the people will give our normal schools four years to prepare each type of teacher—rural-school, primary, intermediate, upper-grade, or junior high-school and high-school; if they will provide scholarships for qualified students seeking entrance to these normal schools; if they will limit teachers’ licenses to graduates of these normal schools; if they will insist that the normal school is to train teachers, and that this job is big enough and important enough to absorb all of its energies; if they will insist that every normal school is operated for the benefit of the whole people and not for the pecuniary advantage of the local community in which it has been placed; if they will determine, in consequence, that all the schools of every community having a normal school shall be available as laboratories of teaching, and will be firm in their determination to the point of moving the school to another place if the profiters are obstinate; if they will pay to normal-school instructors salaries just a trifle higher than instructors in any other group of higher or professional institutions receive (for this, in view of their tremendous responsibilities, is no more than the due of those who prepare teachers for the public schools); if the people will take these simple steps the problem will be solved, and with it will be solved a host of other irritating and perplexing problems that beset public education.
I have purposely characterized these as “simple” steps, for they are simple. In the aggregate they bear no comparison in difficulty to any one of a half-dozen collective achievements of our people during the past two years: the establishment of the selective draft, the floating of Liberty Loans, the inauguration of the shipbuilding program, the feeding of the Allies, the sending of two million soldiers to France. Nor would the cost be prohibitive, even in this day of high taxes. The nation has spent for intoxicating liquors in the past years no less than $1,500,000,000 annually. It seems that this is to be saved in the future. It will be augmented by the increase production due to the disuse of intoxicants. Let us assume, conservatively, that the available wealth of the nation will be increased by an annual increment of two billion dollars because of prohibition. Where should this increase go? Is it improper to suggest that a fair portion—say one-half—should go to public education? Certainly the public schools have done their share to bring about this consummation.

We are told, of course, that the prime cause of prohibition in this country has been the great development of industry; but other countries have undergone industrial development—are much more thoroughly industrialized even than we are. Yet there seems to be no visible movement toward prohibition. In this country one factor, however, has operated in a measure unapproached elsewhere. For two generations the schools have explicitly and systematically indoctrinated the children of the nation against alcohol. The mills of education grind slowly, but eventually they grind exceeding small.

Is it unreasonable to claim for education one-half of the impending saving? A billion dollars added to our annual educational budget would solve our problem in a trice. We could raise the level of public-school services to a point unapproached and unapproachable by any other nation. We could put into every classroom in the country within a decade—into the rural and village schools as well as the urban schools—a teacher adequately prepared to do in a masterly way the work that that school involves. We could pay to that teacher a salary that would make him not only content but anxious to make the work a real and permanent career. We could pay to the rural-school teacher the differential that is needed to get into these schools and keep in them the men and women who, in these strategic positions, can do more for the future of our country than any other group. We could make our normal schools into great educational West Points, where the best talent that the country produces could be instructed and trained and inspired to do the most important work that can be done in a great democracy.
7.3 Building a still better teaching profession for our times

W. E. Peik
Dean, College of Education, University of Minnesota

Source: W. E. Peik, The education of teachers as viewed by the profession. Proceedings of the National Commission on Teacher Education and Professional Standards, National Education Association of the United States, 1948, pp. 9–17. (Official group reports of the Bowling Green Conference held at Bowling Green State University, Bowling Green, Ohio, June 30–July 3.)

The assignment to us here is extraordinarily crucial and timely. At Chautauqua, two years ago, we emphasized the emergency in the supply of teachers. At Oxford, we stressed the improvement of teaching service for advancement of democratic standards of living through education.

Here at Bowling Green, we are now to come to closer grips with teachers’ full, pre-service preparation for professional service.

We shall need a working philosophy of education as a frame of reference for teacher education. What is the over-all objective of teacher education today? I tried to state it for my own satisfaction recently and this is what I put down:

We must build to still higher levels of competence a profession of teachers. They must be better selected; broadly, functionally, and well educated; especially competent, responsible, and scholarly in teaching fields. They must be zealous and professionally both more informed and more skilled than they have been before. These competencies they must have that they may educate the children of America to their full growth and development that as future citizens and free men they may carry forward the democratic way of life in our homes, in our communities, and in our country; may earn security for themselves and become, also, more able than we seem to be, to meet their full responsibility to world citizenship; then, if there still be time and opportunity, may prevent any world war from ever happening again.

In ability, we can be matched many times from a great profession of 1,200,000 elementary, secondary and higher, public and private teachers, which includes the greatest minds of our times. However, in official leadership (which the contingent here holds at this time), in legal and organizational positions, you leaders can barely be matched once over again. It is that leadership, your representativeness of state and national positions, that makes this conference significant for American education. It is our new world role as a leading nation that makes this conference important now. It is the world in which we are leaders, and which is in part a rubble heap, for the most part miserable and three-fifths illiterate, while it is sitting on an atomic bomb, that makes this meeting of American teachers important. It is the fact that, in this world leadership, democracy itself is on trial, that it often appears to be bungling along, and that it may not always have the chance to bungle along in the future, which makes this conference of teachers important. Never in the history of teacher education in our nation have so many leaders sat together to review the basic, undergraduate, professional education of American teachers in
terms of the job that lies ahead. That is why Bowling Green must not fail the American teaching profession and through them, perhaps, America’s destiny in world relations.

**EVALUATE TEACHER PREPARATION, INSTITUTIONAL ACCREDITATION, AND CERTIFICATION STANDARDS**

As practitioners who are in daily contact with our work, we must develop the standards and content of our preparation. Let us examine a few of these about which we ought to be united throughout the nation:

**Require selection and limitation of supply to demand**

Society has not screened out sufficiently those who are not endowed for so high a service and so difficult a vocation as that of the teacher. Too many teachers still come from the lower half of high school senior scholastic ability. Too many still do not have those human qualities which do endear good teachers to pupils. A few care too little about ethical or cultural standards. With the oversupply of secondary teachers, but not of well-selected, completely prepared secondary teachers which is developing now, state departments and colleges must have the wisdom and courage to do something more than they have in the past about selection and oversupply.

Bowling Green must show the way. Have we the courage to speak plainly to our institutions? Seventeen hundred junior colleges, arts colleges, teachers colleges, and universities can destroy the quality, status, and support of our profession. No single institution of our land has the right to prepare just anybody for teaching, in any convenient way, in any amount, unless it meets actual needs of supply, high standards of selection and preparation, which the teaching profession itself should now promote with specificity and with unanimity.

**Evaluate and promote the teacher’s education and training for his duties as a teacher**

The teacher’s education consists of four closely related areas: (1) the common general education of all; (2) additional professionalized general education for respective jobs; (3) specialization in teaching fields; and (4) the professional theory and practice of teaching.

**INSTITUTIONAL RESPONSIBILITY AND COOPERATION IN TEACHER EDUCATION**

Teachers colleges are becoming state colleges. Teacher education should not and need not suffer in the process. In fact a state college, larger and broader than a small teachers college, can do a better job of selection, of guidance, of general education, of professionalizing subject matter and of professional orientation and training, because there are larger enrollments for better specialization, for easier adjustment to special group needs, and for more economic unit costs. But the education of teachers must never become a neglected side line in a state college; of this there is danger and evidence of occurrence. The teaching profession is larger than all other learned professions combined. It is a main function of any institution that undertakes it.

Liberal arts colleges, which desire to prepare teachers, must win this right by appropriate provision for it in curriculum reorganization, guidance, selection, supervised student teaching, clinics for special child study, strengthened departments of education, and participation by their staffs in state associations, public school conferences. Teacher education is professional
education in addition to liberal education. If a faculty does not wish to do vocational preparation, and does not mingle with the profession, it should not want to prepare teachers for certification.

In general, there should be fewer but stronger, more carefully accredited teacher preparing institutions of all types in our country. A college or department of education must cooperate with the whole institution for teacher education in a fine spirit of leadership and coordination. The whole institution must cooperate with the department or college of education in the same spirit.

The time for making faces at each other is long past.

Upon the consciences of well-meaning but sometimes erring staffs must be placed the responsibility for retarding development of the professionalization of teaching. The presence of a staff antagonistic to professional preparation, especially if it is in a position to cripple it, should be considered prima facie evidence of a failure to meet standards. Fortunately this situation is clearing up rapidly.

A LONGER PERIOD OF PROFESSIONAL PREPARATION

The pre-service education of teachers within the pattern of adequate general education, professionalized subjects, competency in broad fields, adequate preparation in the theory and practice of education, together with sufficient electives to permit individualized adjustments to interest, special talents, and deficiencies, cannot be done in four years. It requires a minimum of five years. The five-year curriculum for teaching can best be met by an expansion of all elements of the undergraduate pattern described before. I believe it should be met with the award of an advanced professional degree by the professional school itself and not by the graduate school.

I have referred to the size of the assignments in terms of number of teachers, pupils, and laymen to be reached; in terms of the special problems of action-planning, publicity, public relations, unification of our profession through nationwide organization; the trimming of supply to demand; better selection, functional general education, broad specialization for the teacher’s work, more complete professional orientation and training; the extension of the period of preparation for all teachers; better graduate training for research specialists; and to other problems that are related to these. I believe that the signs are favorable and that an outstanding contribution will be made by us. We must plan to build a still stronger profession of teachers for our times.

NOTE

1 Excerpts from abstract of conference keynote address.
7.4 On the education and certification of teachers

Arthur E. Bestor, Jr.
University of Illinois

The division between elementary and secondary education on the one hand and higher education on the other is an administrative fact, natural and probably inescapable. In recent years in the United States, however, it has been converted into a momentous intellectual schism, threatening the soundness of our public educational system and even the intellectual welfare of the nation. The schism has spread to the universities, where the education of teachers has come almost completely under the control of departments or colleges of education, so-called, which are affected little, if at all, by the educational thinking of the rest of the university faculties.

This process has been facilitated by a misuse and misapplication of the word education. The Department of Education actually concerns itself with “the art, practice or profession of teaching; especially, systematized learning or instruction concerning principles and methods of teaching.” The quoted words are the dictionary definition, not of education, but of pedagogy. What calls itself a Department or College of Education is, properly speaking, only a Department of Pedagogy.

This is not a mere matter of words. The faulty terminology at present used has warped, in subtle but dangerous ways, the thinking of almost everyone in America concerning public educational policy. The fact—obvious, undeniably, and yet forgotten—is that the university as a whole is concerned with education. Every department in it is a department of education in the legitimate sense of that word. My own department is actually a Department of Education in Historical Thinking. The term Department of History is merely a convenient abbreviation of this concept. The division that calls itself a Department of Education is in reality a Department of Education in Pedagogical Methods. It has no right whatever to abbreviate its name to Department of Education and thereby to imply that it has a greater concern with education than some other department.

The abuses to which this faulty terminology has led are numerous and obvious. Taking advantage of the unfortunate laxness of academic terminology, professors of education represent themselves to the general public as the only members of university faculties who need to be consulted with respect to the ultimate aims and purposes of education. And they have contrived to put across the completely unfounded notion that the proper way to prepare for a career in teaching is to take course work in education, so-called, that is to say, in pedagogy.

Let me not be misunderstood. Pedagogy itself—that is to say, the careful investigation of the processes of teaching and learning—is a legitimate field of research. Important work has been done, and it must continue to be done, in investigating the psychology of learning, in developing effective textbooks and teaching aids, in experimenting with classroom procedures, in adapting instruction to students of differing intellectual capacity. As a teacher of history, I am directly interested in every improvement that increases the effectiveness with which history is being taught. But the effective teacher of history requires many qualities of mind and personality, many varieties of knowledge, and many intellectual skills, among which pedagogy is only one.
Obviously every teacher must have some knowledge and skill in pedagogy just as a doctor
must have some adeptness at what we call “bedside manner.” It is far from certain that the best
way to acquire these skills is by listening to lectures about them. But granting that it is, such
courses are not the central thing in the preparation for either profession. What counts in a doctor
is his knowledge of medicine, and what counts in a teacher is his knowledge of the subject he is
teaching. To expect to produce a good teacher by training him mainly in pedagogy is as foolish as
to expect to produce a good doctor by loading him down with courses in bedside manner. And yet
at one midwestern university there is a course entitled “Science in the Elementary School,” the
catalogue description of which says frankly, “no science background is assumed and no attempt
is made to cover content.” If medical schools were run as colleges of education are, we would all
be done to death by cheery and plausible doctors who would know all about how to practice
medicine but who would not be quite sure whether human beings have gizzards or not.

The preparation of teachers for the public schools is one of the most important functions of the
American university. It is a function of the university as a whole. It will never be satisfactorily
performed until it is performed by the university as a whole. The fact that it has largely been
deleagated to the department or school or college of education is a principal cause of the alarming
anti-intellectualism of so much public education today.

Faculties of liberal arts and sciences must retrieve their past mistakes. At the undergraduate
level the education of the future teacher should be an education in the liberal arts and sciences.
This ought to be self-evident. The ideal of liberal education is to produce men and women with
disciplined minds, cultivated interests, and a wide range of fundamental knowledge. Who in our
society needs these qualities more than the teacher? We increasingly recognize that the doctor,
the lawyer, and the engineer, if they are to achieve true professional eminence, must receive
balanced training in many intellectual disciplines which are not directly related to their profes-
sions. How much more does a teacher need such an education? For him the fundamental
intellectual disciplines are not supplements to, but the very essence of, his professional stock in
trade. The teacher never knows when he may be called upon to give instruction in any or all of
them. The students whose work he directs have a right to expect of him a genuine and sympa-
thetic understanding of their various intellectual interests and ambitions. The last profession in
which narrow vocational considerations should be allowed to interfere with thorough and well-
balanced undergraduate preparation in the liberal arts and sciences is the teaching profession.
Opportunity to satisfy minimum pedagogical requirements should be provided through electives
that are a normal complement of a college program of liberal education, but under no circum-
stances should the department of pedagogy be permitted to exercise any sort of control over the
undergraduate programs of prospective teachers.

Continued training in the fundamental intellectual disciplines is the recognized and proper
purpose of graduate work. American universities, it seems to me, have failed, and failed most
miserably, to apply even rudimentary common sense to the problem of devising a sound and
useful graduate program for public-school teachers. We force the teacher to choose between a
research program that is thorough and scholarly but too highly specialized for his needs, and a
pedagogical program that is superficial and blatantly anti-intellectual and that solemnly and
tediously reinserts him in vocational skills he already possesses. The university ought not to
compel the teacher to choose between such unacceptable alternatives. It should offer him a
program that satisfies the highest academic standards and at the same time faces realistically
the actual facts of secondary and elementary school teaching.

We must begin by considering the actual situation of the public-school teacher. He is usually
called upon to teach two or more distinct disciplines. Even in a single course he ought to be
bringing to bear upon the subject in hand appropriate information from other fields. A wide range
of accurate knowledge is his most useful asset, rather than an intensive knowledge of a limited
though rapidly advancing segment of learning within which he may hope to make original
contributions of his own. In simplest terms, the graduate work of a school teacher ought to be a
prolongation and deepening of the liberal education which he received (or should have received)
as an undergraduate. The university ought to provide him an opportunity to continue that liberal
education for as long as he is willing to pursue it, and it ought to reward him with a suitable degree
for conscientious and thoughtful work when rationally directed to that end.

Let me illustrate by a specific example. A student, let us assume, has received a four-year
liberal education, in the course of which he has met the pedagogical requirements for teaching.
He has majored, perhaps, in history, and has done a considerable amount of work in English. He
has taken introductory courses in the sciences, economics, and political science, and acquired a
reading knowledge of one foreign language. His first teaching assignment is to a course in the
social studies, to a course in English, and to one in algebra. He is to return for several summers to
the university for advanced work. What should the university encourage him to do?

The university should permit him, first of all, to take courses that will really round out his
knowledge of the various fields of history. For this purpose many undergraduate courses may
be more appropriate than the graduate courses offered to research students, and he should be
permitted to elect these. When he has completed a sound program in history, he should be
permitted to go back to the point at which he dropped mathematics in college, and work that field
up systematically in the way in which undergraduate majors in mathematics would do. So it
should be with each of the fields in which he has done previous work, or in which he is required to
teach, or in which, perhaps, he develops an interest for the first time.

The results of such study would be an exceptionally well-prepared teacher. More than that, the
results would be a liberally educated man or woman, with a far deeper and wider range of
knowledge than a four-year undergraduate program could give him. Study directed in such a way
and to such ends is advanced study, no matter what parts of it may have been pursued in
nominally undergraduate courses. It is the kind of education which a university should be proud to
offer, and which it has a legitimate right to reward with an advanced degree. A student who
pursues such a well-though-out program for a full academic year beyond college graduation and
who brings his command of two subjects up to certain pre-established standards should receive
a Master’s degree. A student who pursues it with distinction for three years beyond college
graduation and who brings his command of five subjects up to the standards set should be
entitled to a doctorate.

Much careful thought must go into the establishment of these standards in each subject. In
order to receive a degree, a student should be required to demonstrate, in each proffered subject,
a comprehension at least equal to that which an able undergraduate might be expected to obtain
through a strong major program in the discipline. Course credits might aggregate about 30
semester hours, including undergraduate work. But the number of courses should not be the
principal criterion. A comprehensive written examination in each of the subjects offered for the
degree would be indispensable. In addition, an oral examination for the doctorate should cover all
the five fields presented. A careful reading of certain basic works—the classics of the discipline—
should be specifically required and tested. No thesis would be submitted for either degree, but a
student should have been required to write at least one substantial original essay in each of his
fields during the course of his studies, and these should be part of the record upon which his
degree is awarded.

The traditional research program of the university, and the teaching program that I have just
described, should be considered parallel but distinct. Both should be under the administration of
the graduate school of the university, but the degrees ought to be different. Corresponding to the
traditional degrees of M.A. and Ph.D. which would continue to be awarded in the research pro-
gram, the university might make use of the degrees of Master and Doctor of Education (M.Ed.
and Ed.D.) for the teaching program. These degrees, of course, already exist. The present pro-
posal, however, would put them under the jurisdiction of the university as a whole, not the
department of education or pedagogy, and would permit a student to earn them by work in any regular department of liberal arts or science in the university.

This new all-university faculty would also assume direct authority over the curriculum in the demonstration and laboratory schools which the university maintains. To the general public a university school signifies an institution of elementary or secondary education devoted to the ideals of science and scholarship for which the university stands. It must be made precisely that. Its program should be determined by scholars, scientists, and educationists together, and it should concentrate its experimental work upon the problem of effectively teaching the basic intellectual disciplines, organized as they are in the real world of science and learning.

Advanced research in educational problems will be conducted, as it ought to be, by the university as a whole and on an interdisciplinary basis. In other words, psychologists, sociologists, and statisticians will be asked to collaborate in investigating various problems of teaching and learning. Historians, political scientists, and economists will co-operate in studying various aspects of educational administration. The university will serve public education, not by delegating its responsibilities to a department of pedagogy, but by itself providing the opportunity, the facilities, and the funds to bring specialists from various disciplines together for co-operative research without detaching them permanently from the departments to which they belong.

One great barrier stands in the way of a rational program of teacher training—the certification requirements which are imposed by the state. These requirements are, in reality, special-interest legislation—a kind of protective tariff—enacted for the most part at the behest of professional educationists. As the very first step toward educational reform, citizens, scientists, scholars, professional men, and classroom teachers must unite in demanding that the legislatures of the 48 states review, carefully and realistically, the statutes governing the certification of teachers. The present laws must be replaced by ones which will protect the schools against incompetent teachers rather than the professors of pedagogy against losses in enrollment.

Looked at from the point of view of logic or common sense, the present arrangements for certifying teachers are completely topsy-turvy. Local school authorities, who can interview teachers individually as well as examine their credentials, are in a far better position to judge a candidate’s probable skill and competence as a teacher than can a bureaucrat who works solely from records of courses taken. Conversely, an agency of the state is far better equipped than a local school board to determine a student’s competence in his chosen subject, for it can compare his academic record with hundreds of others, it can administer standardized examinations, and it can call upon specialists in all the fields of knowledge for advice and assistance. Under the existing system, however, the responsibilities are completely reversed. The matters that local authorities are competent to determine for themselves are precisely the ones that the state educational bureaucracy insists on controlling from above; and the kinds of minimum requirements which the state is in the best position to enforce are precisely the ones that are left largely to local discretion, or to quasi-official accrediting agencies.

The first step to reform is to clear the statute books of those provisions which specify a fixed number of hours in education (that is, in pedagogy) as a requirement for certification. This means simply dethroning these requirements from their peculiarly privileged position. Then a new system must be worked out which will give assurance that a certified teacher is both proficient in teaching and well-prepared in the subjects he or she is to teach.

Different certificates should deal with these different matters. One certificate should testify to the teacher’s proficiency in teaching. There ought to be several ways of earning this certificate. An experienced teacher ought to be granted it simply upon presentation of satisfactory evidence of a successful teaching career of a specified length of time. For a candidate without previous experience, successful completion of a period of practice teaching should be the principal requirement. The institution that supervises practice teaching usually specifies certain pedagogical courses as prerequisites, hence the state has no need to lay down pedagogical course
requirements of its own in granting certificates of teaching proficiency. Provision should be made for students without either experience or practice teaching to obtain a temporary certificate enabling them to offer instruction in specially designated schools, which would guarantee to give on-the-job training and special guidance and supervision to those without experience. Such programs might well be financed by the state to aid in the recruitment of teachers, or they might be conducted by the extension departments of universities. After completing a specified period of teaching under such conditions, an instructor should be entitled to a permanent certificate of teaching proficiency. An arrangement of this kind would enable the schools to draw upon a large and brilliant group of liberal arts graduates who are at present excluded from public-school employment by unjustifiably arbitrary pedagogical requirements. After the basic certificate in teaching proficiency has been earned, further course work in pedagogy should be entirely optional with the individual teacher.

Another certificate should be provided for each of the fundamental disciplines of public-school instruction. Ideally these certificates should be granted on the basis of state-administered comprehensive examinations in the subject, periodically offered to all persons who believe themselves qualified. There should be at least two levels of such examinations, one leading to limited, the second to advanced certification in the subject or discipline. Pending the development of such examinations, limited certification might be granted on the basis of 15 or 20 semester hours of college work in the subject, advanced certification for 30 or 40 hours. The certification should be in specific subjects rather than general areas. In other words, there should be certificates in history, in political science, and in economics; a teacher of social studies would be expected to possess at least limited certification in two or three of these subjects.

A prospective teacher would be encouraged to meet certification requirements in as many subjects as possible during his undergraduate years. The teacher already in service who returned to the university for advanced work during summer sessions and regular terms would have a definite purpose in view: to bring his certification in the subjects he had been teaching from the limited to the advanced classification, or to secure certification in additional subjects. The recognition or accrediting standards applied to schools themselves could easily be geared to this system of certification. The ideal school would be one in which every course was being conducted by a teacher possessing advanced certification in the subject or subjects covered by the course. Every deviation from this would lessen the standing of the school.

Salary increments could likewise be effectively tied to this scheme. The term “professional growth” frequently appears among the criteria for the promotion and the advancement in salary of teachers. At present this is a vague phrase. It could easily be endowed with a definite meaning. Under the proposed system, a teacher would be giving tangible evidence of professional growth every time he raised his certification from limited to advanced in a given subject and every time he acquired a limited certificate in a new field. Each such step might well entitle him to an increment in salary.

Besides the certificate of teaching proficiency and the certificates in the various subjects, provision would have to be made for various types of special certificates. Elementary school teaching, for example, presents special problems. A certificate in Educational Psychology for Elementary School Teachers, in addition to the general certificate in teaching proficiency, might well be established. Care should be taken to make its requirements clear and specific. This certificate should not be granted for a mere potpourri of pedagogical courses, but only for a carefully designed program comprising extensive work in the regular academic department of psychology. Another certificate in Educational Administration should also be offered, to be obtained by specified work primarily in the departments of political science (or public administration), economics, and law, with only such work in the department of pedagogy as seemed clearly justifiable. Other special certificates—and several will doubtless be needed—should be set up on analogous principles.
A reorganization of teacher training and certification requirements along the lines here outlined would correct some of the gravest abuses in the present situation. It would bring to an end the aimless accumulation by experienced teachers of credits in pedagogical courses. It would restore to teacher training a realism and a clear sense of purpose that it has lost. It would, in fact, make teacher training “functional” once more.

A new curriculum for the education of teachers, based firmly upon the liberal arts and sciences rather than upon the mere vocational skills of pedagogy, will do more to restore the repute of the public schools than any other step that can be taken. Not only will teachers be adequately trained in the disciplines they undertake to teach, but they will also be imbued with respect for those disciplines and will be prepared to resist the anti-intellectualism that currently threatens the schools. And when the tide begins to turn, young men and women of genuine intellectual interest and capacity will be attracted in increasing numbers into the profession of public-school teaching. They will not be repelled at the outset by being asked to lay aside their intellectual interests and fritter away their time in the courses of the pedagogues. Under a well-ordered plan, the gateway to teaching will be the gateway of learning itself.

NOTE

7.5 The professional standards movement in teaching

Evolution of an idea

*Ralph W. McDonald*
President, Bowling Green State University

The inquiring mind of man has produced several hypotheses as to the forces that determine the course of human events. There are those who have argued that military conquest has largely determined the ebb and flow of world history. There are those who have held that the mighty forces of nature—the sea, the mountains, the minerals, the elements—have really made our civilization or lack of it. A closer and more penetrating analysis of the evolution of human society brings us closer to the truth, in my judgment. The most powerful force in the shaping of human destiny is an idea.

On the canvas of history the picture of human progress is painted in the strokes of ideas—great ideas, lesser ideas, and ideas so fine in their tracing that they seem to disappear in the halo or the shadow. The entire canvas, however, is done in ideas.

The professional standards movement in teaching is an idea on the march. It is the idea that teaching is truly a professional endeavor, and that in the public interest the rank and file of qualified practitioners engaged in teaching must be organized as a profession to determine and apply appropriate standards to govern the selection, preparation, licensing, ethical conduct, and service of those who enter upon this profession.

**CONTRIBUTION OF OTHER PROFESSIONS**

The concept of practitioner responsibility for professional standards did not originate in the field of teaching. The same basic idea had long before been accepted and implemented in the fields of medicine, dentistry, law, and other major professions. Practice in these fields has become truly professional as the same basic idea had moved to fruition in the respective areas of service. Although teaching is in fact the mother of all the professions, it is years behind the others in becoming a profession. Since 1946, the organized body of American teachers has been engaged in the same kind of evolution or metamorphosis as has been taking place in other major professions in the United States. As individuals, many educational leaders long before 1946 had been striving to improve teacher selection, preparation, certification, and growth in service. Their individual efforts, however, were insufficient to produce widespread and lasting progress.
GROWTH OF THE IDEA

It was only natural that I should carry my driving convictions into the broader relationships with the organized teaching groups of the country.

A necessary first step had already been taken in 1945: an effort to bring the respected and scholarly leadership of American higher education into the working organization of the NEA. One of the major steps in the emergence of all of the other professions has been the establishment of a partnership between the organizations of practitioners and the administrations and faculties of the universities of the country. Medicine, law, engineering, forestry, journalism, and the other major professions had emerged to real professional strength and status as the programs of preparation for those professions had gradually shifted from separate technical schools and institutes to professional colleges on the university campuses, where they gained new strength and stature through the breadth of university life and firm integration with time-honored programs of liberal arts education.

I knew that teaching could achieve major professional status only if the same kind of transition and alliance could be encouraged in the field of teacher education. The NEA Department of Higher Education, the name of which was later changed to the Association for Higher Education, presented the opportunity to develop a broad liaison between the organized teachers at the elementary and secondary levels and the faculty leadership of the great colleges and universities of the country.

FORERUNNER OF NCTEPS—THE CHAUTAUQUA CONFERENCE

The professional standards movement began in earnest when the NEA Executive Committee approved the request of the Committee on Preparation and Certification for an emergency national conference to be held immediately preceding the 1946 Delegate Assembly of the NEA. The Chautauqua Conference came at a crucial time. Conditions in the public schools, particularly as regards teaching staffs, had reached a stage so serious that the word “crisis” was too mild a term to describe it. There had been almost a mass exodus of teachers from the classroom. Figures reported by the U.S. Office of Education revealed that 633,200 persons had quit classrooms in which they had been employed as teachers during the six years preceding 1946. Even more serious was the heavy decline in the percent of college students choosing to prepare for teaching. There had been a widespread effort to get more teachers into the classrooms by lowering the standards of preparation and certification, to the point that in many states any breathing human could legally be employed as a “teacher.” With each downward step in standards more good teachers had left the classrooms and fewer capable students had chosen teaching as a career. In their desperation to keep the schools open, the American people did not seem to realize that they were making matters worse by these actions; and the organized teachers were standing idly by.

The Chautauqua Conference was deliberately structured to produce professional consciousness and professional conscience. For the first time in our history, highly trained primary teachers and high school teachers sat down around the table to consider common problems with scholars from the faculties of leading colleges and universities. At the conference table every person was held in equal respect and his opinions given equal consideration by all others around the table. They were earnest, intelligent leaders from all branches and levels of education in the United States. Every detail in the planning of the conference was geared to produce action. The questions were direct and to the point. Around every table the time was “now.” The questions started with “How . . .” and “In what manner . . .,” instead of “Should . . .” and “Would it be a good idea . . .” Even the revolutionary proposal that the organized teaching profession accredit colleges for
teacher education was approached in the same manner by a carefully selected group under the chairmanship of Ernest Melby.

**NCTEPS IS CREATED**

It is difficult for us to realize ten years later just how revolutionary the Chautauqua Conference approach was. I shall always look back upon that conference and the ensuing events at the Buffalo Delegate Assembly as the American teachers’ finest hour. In one bold and unprecedented series of events, the teachers of this nation overcame more than a century of inertia and staked out the ground upon which the structure of a real profession could be erected, beam by beam and stone upon stone.

The spark that had been kindled in the classroom teachers’ regional meetings became a flaming torch at Chautauqua, and became at Buffalo a continuing lighthouse for the guidance of teaching into the harbor of true professionalism. The heart of Chautauqua was an idea. The idea was the important thing. It is the important thing now. It must ever be the essence of this movement.

**NCTEPS BEGINS ITS WORK**

The work of organizing and developing a program to implement the idea began in earnest after the Buffalo meeting. The newly appointed members of the Commission realized the toil and sweat had just begun. The tasks were many and arduous: Alert the American people to what was happening to their schools and particularly to the teaching profession. Secure complete acceptance of the idea at the very grass roots in all branches of the teaching profession at all levels and in all parts of the United States. Develop goals and policies applying the idea to every major factor related to the practice of teaching, from the recruitment of candidates to the standards covering salaries and working conditions. Conduct research to get the facts on all aspects of the problem and to provide criteria for evaluating progress. Establish cooperative machinery for engaging in direct action at national, state, and local levels. Initiate specific action programs directed to the selection, preparation, licensing, admission to practice, growth in service, and professional service of teachers.

Through national, regional, state, and district conferences and countless meetings at the local level the idea became, in a few short years, a commitment and an article of faith of the organized teaching profession.

**PROGRESS IN THE PROFESSIONAL STANDARDS MOVEMENT**

It was as if the leadership of the organized teachers across the country had been waiting merely for the signals to be called. The leadership, the resourcefulness, and the statesmanship of the officers and executive secretaries of the state education associations began immediately to be felt as a mighty force in carrying the idea forward. Likewise, most of the leaders of the national organizations in education and of the powerful lay allies of the teaching profession were soon joined in the movement. Within two or three years a vast organization for cooperative effort in the achievement of professional standards had come into existence. There were parallel state commissions in nearly all the states. Practically every national association affiliated with the NEA had a special program for the advancement of professional standards. One of the most important groups in American education, the National Association of State Directors of Teacher Education
and Certification, had been nurtured by the Commission to a new stature of national leadership and service.

**Literature**

Imbued with the idea and organized for action, the profession began to achieve results. Within one year from Chautauqua the tide began to turn. The organized teachers began to bring emergency certification under control and to reduce its extent. The downward trend of certification standards, battered and weakened in the years before Chautauqua, was first halted and then reversed in state after state by the determined efforts of an aroused profession. Research studies, such as the annual national teacher supply and demand study by Ray C. Maul, began to reveal hitherto unknown facts about teaching and to focus attention upon the points where action was most imperative. Under the leadership of the Commission, a literature of professional standards began to emerge in the form of policy statements, *The Journal of Teacher Education*, the reports of the national and regional conferences, and numerous other publications. Steadily and surely the upward drive proceeded from Chautauqua to Oxford to Bowling Green to New Hampshire to Indiana to Palo Alto to Kalamazoo to Miami Beach to Albany to DeKalb, and now to Parkland.

**Certification**

From 15 states requiring the completion of a four-year degree preparation for minimum certification in 1946, the number had risen to 31 in 1955. The progress in elevating certification standards has been much wider and deeper, however, than even this impressive statistic would indicate. There is not a state in the Union that has failed to strengthen its teacher certification standards during this ten-year period. Even more important, I doubt that there is a state in the Union which does not have, at the present time, a going and vigorous program of action to elevate still further its teacher certification standards.

**Teacher preparation**

The chief gain in preservice teacher education since 1946 has been the strengthening of the liberal education foundation of the teacher. While a four-year prepared teacher usually has much better training in professional subject matter, the principal gain in his preparation for teaching is in the fact that he is a much better educated person in the broad sense. The most important earmark of the qualified teacher is a broad, liberal education. Even in medicine, law, business, engineering, theology, and other occupations that have risen to professional stature, the fundamental requirement of a broad, liberal education is practically universal, with the specialized professional preparation built upon or interwoven with this foundation. In preparation for teaching, sound liberal or general education is even more essential and should be even broader, deeper, and more thorough.

The elevation of preparation and certification standards has produced substantial improvement also in professional welfare, financial compensation, and conditions of service of teachers. Higher standards for teaching have produced a higher level of respect and prestige for those engaged in teaching. Parents and citizens generally have been willing, yes insistent, that more adequate salaries and better working conditions be provided for those engaged in teaching.

The march of an idea has become the forward salient of the great body of American teachers rising ever nearer to the level of a true profession.
DEVELOPMENT OF NCATE

From the beginning, even before Chautauqua, the core of the movement has been to establish and secure adherence to high standards in college programs for the preparation of teachers. As in other occupations that have achieved professional status in our democratic society, the voluntary professional accrediting process is the only effective means of achieving this goal. The steps in this direction have, in every profession, been the most difficult to achieve. Relationships in this area of progress are the most delicate, and the cooperation of all sincere interested groups is imperative. Progress in this area is the most profoundly significant contribution of the professional standards movement in teaching.

After long, patient, and cooperative efforts on the part of the Commission and AACTE, the latter agreed to yield the professional accrediting function to a broadly representative council rooted in the organized teaching profession of the United States. In April, 1951, I invited key representatives of the AACTE, NCTEPS, the National Council of Chief State School Officers, the National Association of State Directors of Teacher Education and Certification, and the National School Boards Association to meet at NEA headquarters. At this meeting and a meeting later that year, the National Council for Accreditation of Teacher Education was forged out and came into existence upon the official confirmation of the groups whose representatives had assembled. The Council was to begin its work on July 1, 1954. Through a stroke of great good fortune, W. Earl Armstrong became associated with the Council as its executive director a few months prior to the date when the Council was scheduled to take over the national professional accrediting function. Under the leadership of Mr. Armstrong the Council is on the way to achieving the structure and status necessary to perform its valuable function.

ROLE OF PROFESSIONAL ORGANIZATIONS

I should like to add a fifth major problem area to our agenda, not just for this conference, but for all conferences and all organized efforts to achieve professional status and professional standards in teaching. This problem area is perhaps the most crucial of all. It relates to the development of a strong and truly professional organization of the teachers in this country.

The National Education Association is one of the world’s great organizations. Its progress is a source of pride to all of us. It is but a mere beginning, however, toward the kind of professional organization we need and must have if teaching is to rise to a professional level in our democratic society.

Our professional membership dues, when national, state, and local associations are considered as one, are pitifully small when measured against the needs and the demands of a truly professional organization. A doubling of the present level of our professional dues would still leave us far short of the financial support essential to a professional organization program. For one, I believe the teachers of the United States are ready and willing to go forward in this matter. Certainly we can blame no one but ourselves if we claim to be a profession and fail to provide even the minimum financial resources for a professional program.

Another fundamental weakness in our professional organization is that it is not professional by its own standards of admission to membership. You may recall, as I do, the great furor a few years ago when President Roosevelt’s dog, Falla, was reported to have been duly admitted to membership in the NEA. How can we claim to be a profession when anybody, anywhere, with any qualifications or no qualifications, is admitted to membership in our so-called professional organization by merely turning over a five-dollar bill for membership dues? For so long as we continue such an admission policy, we shall ipso facto convict ourselves of being hypocrites and traitors to our own professed belief that teaching is a profession. Have you tried to join a medical society
lately? Can you go to your local bar association and become a member merely by paying a fixed sum of money as annual dues? Can you join the American Institute of Architects or any of its local branches and call yourself an architect by the mere gesture of paying a sum of money and giving your name to the secretary? Of course you can do none of these things, because those organizations are professional bodies.

I challenge this conference and the entire leadership and membership of our profession in the United States to place as the number one item on your agenda this question: When are we going to start making an honest effort to achieve a truly professional organization of teachers in the United States?

As I pointed out in the beginning of this presentation, the professional standards movement in teaching is the march of an idea: the idea that teaching is truly a professional endeavor, and that in the public interest the rank and file of qualified practitioners engaged in teaching must be organized as a profession to determine and apply appropriate standards to govern the selection, preparation, licensing, ethical conduct, and service of those who enter upon this profession.

Dedicated to this idea, let us say with Jamie Sexton Holme:

Do not come and look for me, I shall be gone;
My bed will be empty, my door standing open—
I have a pilgrimage to make before the dawn!

There is a hill against the far horizon,
Where the heavens dip down, and at last disappear.
If I climb to the top, when the stars are just setting,
I know I can reach them, they will be so near!

7.6 National Teacher Examinations (NTE)

David J. Fox
City College, City University of New York

PROFESSIONAL EDUCATION EXAMINATION
(Sample of 6 questions)

1. The high school of today may be considered the common school, just as in earlier days the elementary school was the common school in the United States. This statement is true because
   (A) more students entering high school still need instruction in basic reading and arithmetic skills
   (B) the great majority of American youth attend high school
   (C) high school curricula have become stabilized after a period in which many new courses were added
   (D) more students now continue their study into college
   (E) students of higher social class attend college preparatory academies

2. A very young child learns that the small, furry, purring objects in his house is a "kitty." While visiting another house, this child points to a small dog there and says, "Kitty." This illustrates
   (A) immediate reinforcement
   (B) simultaneous discrimination
   (C) an unconditioned response
   (D) primary stimulus generalization
   (E) secondary stimulus generalization

3. It has been found that intellectually gifted children tend to surpass average children in
   (A) personal and social adjustment
   (B) physical size and health
   (C) social maturity and poise
   (D) all of the above
   (E) none of the above

4. The recommendation that a poem be read over in its entirety before memorizing individual lines illustrates an awareness of the principles of
   (A) proactive inhibition
   (B) gestalt organization
   (C) massed practice
   (D) secondary reinforcement
   (E) retroactive inhibition
5 Within learning theorist’s frame of reference, probably the best way of approaching the organization of subject matter is to move from the
(A) familiar to the unfamiliar
(B) general to the particular
(C) logical to the psychological
(D) societal to the individual
(E) complex to the simple

6 Which instrument would be most desirable for testing the general mental ability of a second-grade pupil, aged seven years three months?
(A) Lorge-Thorndike Intelligence Test
(B) Goodenough Intelligence Test
(C) Vineland Social Maturity Test
(D) Wechsler Intelligence Scale for Children (Revised)
(E) Wechsler-Bellevue Scale

ANSWER KEY

1 B  2 D  3 D  4 B  5 A  6 D

Mathematics education
(Sample of 7 questions)

1 The chief way in which programs for arithmetic teaching in most public school systems differ today from those of fifty years ago is in
(A) rejection of drill and memorization
(B) use of computers
(C) integration of arithmetic with other curriculum areas
(D) stress upon social utility
(E) emphasis upon mathematical meanings

2 Select from the following number statements the one statement in which the mathematical sign < would be appropriately placed within the circle.
(A) 4 + 9 O 8 + 5
(B) 51 + 40 O 10 + 80
(C) 64 − 16 O 41 + 13
(D) 20 + 40 O 30 + 10
(E) 5 + 16 O 17 + 4

3 The “3” in the upper right-hand corner of a newspaper page denotes the
(A) ordinal meaning of the number
(B) cardinal meaning of the number
(C) total collection at a particular point
(D) place-value
(E) fractional part of the total paper

4 The associative law in the process of multiplication states that
(A) a × a = a²
(B) \((a \times b) \times c = a \times (b \times c)\)
(C) \(a \times b = b \times a\)
(D) \(a \times (b \times c) = (a \times b) + (a \times c)\)
(E) \(a + b \times a = a + a \times b\)

5 A student subtracts 3y from 5y and obtains the answer 2. Her error probably stems from the failure to recognize the meaning of the
(A) additive inverse postulate
(B) associative postulate
(C) commutative postulate
(D) distributive postulate
(E) generalization postulate

6 On a number line, the sum of a number and its inverse is always
(A) greater than either number
(B) a positive number
(C) zero
(D) the greater of two numbers
(E) one

7 The pupils in your class are having difficulty understanding what you are teaching. Of the following, it would be least desirable to stress
(A) the meaning of mathematical concepts
(B) rigorous proof of mathematical principles
(C) motivation for mathematical principles
(D) applications of mathematical principles
(E) the need to practice the mathematical processes involved

7.7 New Jersey’s alternate route to certification

Saul Cooperman and Leo Klagholz

Source: Saul Cooperman and Leo Klagholz, New Jersey’s alternate route to certification. Phi Delta Kappan, 66(10), 1985, pp. 691–695

By next fall, New Jersey school districts will be able to offer the first district-administered training programs in the U.S. leading to teacher certification. The architects of this controversial program discuss its genesis and implementation.

The blunt fact is that many of our teachers are not properly qualified to handle the responsibility we have placed on them . . . This is, in my view, the major weakness of American education.

Sterling M. McMurrin, Former U.S. Commissioner of Education, 1963

Nothing in American education is in greater need of reform than the way we educate and certify classroom teachers.

Emily Feistritzer, 1984

In September 1985, local school districts in New Jersey will be able to offer the first district-administered training programs in the U.S. leading to teacher certification. The districts offering such programs will be able to hire on provisional contracts college graduates who have not been certified through traditional education programs and who have passed competency tests in the subject areas they are going to teach. Moreover, these districts will be able to recommend for state certification those individuals who successfully complete the district-administered programs.

This alternate route to certification is the outcome of more than two years of and discussion of teacher preparation and certification in New Jersey. But, in another way, this alternate route reflects 20 years of thinking about the need to reform teacher evaluation in the U.S.

Over the last quarter-century, critics of teacher education have played only minor variations on the same themes. These critics have complained that students majoring in education do not rank among the most academically talented, that both the quality and the quantity of education courses required of majors make for an inferior college education, and that districts are able to grant “emergency” certification to people not adequately prepared to teach—a situation that undermines attempts at school reform.

As long ago as 1963 the critics also began to suggest alternatives to the teacher preparation programs offered by colleges and universities. In The Miseducation of American Teachers, published that year, James Koerner suggested “giving local boards complete freedom in staffing their school” through “some system of qualifying examinations whereby teachers, in order to be licensed, would demonstrate their mastery of the subject they propose to teach.” Such a system “could operate in a number of different ways,” Koerner wrote, “but the principle of demonstrated mastery would be paramount whatever the other details.”
Koerner felt that this kind of system—combining a qualifying examination and a demonstration of teaching ability—could provide an antidote for both “the low level of teaching that many communities now get with fully certified and licensed teachers” and “the tenuous connection between the training that teachers are exposed to and the performance they turn in on the job.”

Whatever system of licensing prevails, the great majority of new teachers will undoubtedly continue for the indefinite future to come through organized programs in colleges and universities. An examination system would merely shift the emphasis for admission to teaching from stipulated preparatory programs to demonstrated ability, would afford a possible means of making teaching an open instead of a closed field, and would exert substantial pressure on the formal programs in the direction of high academic standards.

If anything has changed since 1963, it is the possibility of implementing such a plan. At the time Koerner wrote about an alternate system of certification, he rejected his own proposal as politically impossible. A “free market for local boards in hiring teachers might on balance be a great gain for public education,” he said. “Of course, no such thing is going to happen.”

More recently, the Education Commission of the States recommended that “state certification rules be sufficiently flexible to encourage service in the public schools by qualified persons from business, industry, the scientific and technical communities, and institutions of higher learning.” Similarly, Donna Kerr suggested that we test an alternative to the current certification system that would allow students who score in the top 10 percent on the National Teacher Examinations to enter teaching without taking courses in education.

Clearly, educators are more open to change today than they were in Koerner’s time. An alternative to traditional teacher preparation programs is more than possible today. It is happening in New Jersey.

New Jersey embarked on the process of creating this alternate route to certification in July 1982, when the state board of education expressed concern about the procedures by which “emergency” certification was being granted. The Department of Education responded to the board’s concern by initiating a comprehensive examination of procedures for teacher preparation and certification in New Jersey. In the main, the Department of Education arrived at the same conclusions that similar studies by other researchers have yielded.

QUALITY OF EDUCATION MAJORS

One area on which the New Jersey study focused was the quality of students entering teacher education programs in the state. In 1982 the Scholastic Aptitude Test (SAT) scores of New Jersey high school graduates who planned to major in education were lower than those of graduates who planned to major in 22 of 24 fields of study at the college level. Moreover, among the high school seniors who intended to major in education and who had been admitted to community and state colleges in New Jersey (which provide 70 percent of all new teachers hired in New Jersey from in-state institutions of higher education), 19 percent scored 299 or lower on the verbal portion of the SAT, 60 percent scored 399 or lower, and only 12 percent scored 500 or better on this 800-point subtest. In 1982 the average score on the verbal portion of the SAT for all New Jersey high school students was 416.

Nationally, students who major in education don’t do much better. For example, SAT scores in 1982 for students preparing to teach were 80 points below the national average. Not surprisingly, the New Jersey Department of Education found itself concurring with Ernest Boyer’s conclusion that U.S. schools “cannot adequately prepare the coming generation if the least able students enter the profession.” As Jere Brophy has suggested, effective teachers
“are probably brighter and more dedicated than average.” He added that effective teachers need to be brighter because they must engage in complex tasks, such as planning, analyzing, organizing classroom time, and suspending judgment.15 If the least-able college students decide to become teachers, will they be likely to address such complex tasks in ways that will excite children and motivate them to learn?

U.S. schools must educate young people to participate effectively in a high-tech society. Thus the first question posed by the New Jersey Department of Education was, How can we attract more academically talented people to teach in our public schools and identify those among them who have the personal characteristics that suit them to this task?

INCONSISTENT PREPARATION

The Department’s study of teacher preparation and certification in New Jersey brought to light another concern as well: the widespread inconsistencies among teacher preparation programs with regard to the coursework required of students. For example, a survey of the six colleges that prepare a majority of the teachers employed in New Jersey schools showed that these colleges listed 120 education courses and that some colleges were requiring education majors to take courses not even offered by the other colleges. Such inconsistencies suggest a lack of consensus on what knowledge is essential for beginning teachers and on which qualities characterize effective teachers.

This finding in New Jersey is in step with other research on consistency among teacher education programs. Feistritzer has noted that the courses included in “too many teacher education programs . . . are ill-defined and impractical.”16 Boyer has suggested that education majors be required to take a four-year program of general academic study, followed by a fifth year of coursework in a carefully defined education core curriculum.17

Nor is concern over consistency across teacher education programs a particularly recent phenomenon. As early as 1963, James Bryant Conant noted that students who completed the sequence of education courses in one college may not have considered “the same, or even a similar, set of facts or principles as their contemporaries in another institution even in the same state.”18

From its own survey and the observations of other researchers, the New Jersey Department of Education saw a clear need to identify a body of knowledge essential to all beginning teachers. This would be the point at which the Department would begin to build its alternate route to teacher certification.

“EMERGENCY” CERTIFICATION

Since 1942, a system of “emergency” certification has allowed New Jersey school districts to hire unqualified individuals to teach, if certified individuals are not available. Nearly 20 percent of all newly employed New Jersey teachers in 1982 had entered the education system in this fashion—many of them lacking adequate subject preparation as well as professional training. In some cases, individuals hired on emergency certificates did not even have college degrees. Emergency certification was a sink-or-swim situation; despite their lack of professional preparation, emergency teachers were guaranteed neither in-school support nor necessary professional training. Further, school districts could turn to this weak alternative system only when there was a quantitative shortage. There was nothing they could do when the quality of certified candidates was poor, except employ them as teachers.

As early as 1963, Conant condemned substandard certification. “To anyone who takes state
requirements seriously, this is surely a national scandal,” he wrote. One of the most important functions of alternate certification in New Jersey will be to replace emergency certification in all but a few specific fields: special education, vocational education, bilingual education, and English as a second language.

Ironically, while in case of shortage New Jersey school districts could assign unprepared teachers to subjects they were unqualified to teach, without support or training, the New Jersey Department of Education was receiving a steady stream of inquiries from people who were interested in teaching in the public schools and who had talent and knowledge in those very subjects. These people included accountants and mathematicians, as well as teachers in colleges or in private schools. But unless there was a teacher shortage, and regardless of the quality of certified applicants, these people could not be considered for teaching positions—this at a time when the real “emergency” is one of quality as well as quantity.

THE INITIAL PROPOSAL

After carefully studying the problems inherent in the New Jersey teacher certification process, staff members of the Department of Education developed a proposal for an alternate route to certification. This proposal was intended to begin a process of public development of a program to open classroom doors to talented and enthusiastic but uncertified individuals. However, unlike the unstructured nature of emergency certification, this alternate route would provide a rigorous, district-administered training program. The proposal was first announced to the public in September 1983. Among its suggested reforms were:

- a clear definition of the coursework essential for all beginning teachers;
- a more careful definition of effective teaching, which would be used both to improve the quality of teacher education programs in colleges and universities and to shape the district-administered training program;
- the replacement of emergency certification (except in a few specified teaching specialties) with a carefully developed, rigorous alternative to college teacher training programs, intended to attract talented college graduates who had not been certified through such traditional programs; and
- the establishment of new standards that would require all prospective teachers in New Jersey to have bachelor’s degrees and to demonstrate “content competency” on tests covering the subjects they intend to teach.

THE OPEN PROCESS

By attending to the wide range of opinions, concerns, and experiences represented by these interests, the Department staff was able to strengthen the proposal. The open process for defining the alternate route also convinced almost all the interests that the final proposal addressed their particular concerns. Indeed, some of the groups most vociferously opposed to alternate certification when the proposal was first announced have since become supporters of the plan.

The Boyer Report

To identify the basic knowledge and skills essential for all beginning teachers, New Jersey Gov. Thomas Kean appointed a panel of 10 distinguished leaders in teacher education, headed by
Ernest Boyer.21 The mission of this group was to determine (1) what things beginning teachers must know and (2) how effective teachers teach.

The panel defined an effective teacher as one who has clear goals and who delivers instruction in small increments but at an appropriate pace, interspersing questions to check on comprehension and providing many detailed examples and clear directions. An effective teacher provides sufficient successful practice for all students, sees to it that all students are involved in learning, provides opportunities for independent work, and evaluates the progress of each student, according to the panel. An effective teacher must also be able to stimulate creative thought, help students evaluate what they have learned, and prepare students to use their knowledge wisely.22 The panel concluded that, while most teacher educators would agree with these findings, the knowledge and skills it had identified are often neither “conveyed effectively to new teachers nor applied in practice.”23

To make teacher education more effective, the panel recommended a more practical curriculum—one that moves “from real-life problems to theory, rather than the other way around.”24

The State Commission

As the next step in developing alternate certification, the state commissioner of education appointed an advisory commission.

After lengthy deliberation, the commission almost unanimously recommended “state-approved district training programs.” Its report suggests that local school districts develop three-phase training programs and submit written program plans to the New Jersey Department of Education for approval.25 The three phases are intended to provide progressive training in the knowledge and skills identified by the Boyer panel and in actual classroom teaching. By simultaneously conducting 200 hours of instruction—80 of them before the provisional teacher takes charge of a classroom—and a year of supervised teaching, the district training programs are expected to enable new teachers to integrate theory with practice more readily.

The commission also recommended that each candidate for “provisional” employment as a teacher should have:

- earned a bachelor’s degree;
- passed a competency test on the subject matter that he or she has been hired to teach;
- earned 30 credit hours or have equivalent work experience in the subject that he or she has been hired to teach (at the secondary level) or 30 credit hours in any single field (in the case of elementary teachers); and
- been approved by district personnel after a screening interview that would focus on background, academic experience, and certain ethical and personal characteristics as identified as essential by the Boyer panel.

In September 1984, following extensive public hearings, the state board of education approved this alternative route to certification, as one of several revisions of the administrative code on teacher preparation and certification.

ANTICIPATED BENEFITS

The alternate route to teacher certification seems likely to benefit education in New Jersey in several ways. First, it will expand the pool of qualified candidates from which local school districts can choose their teachers. Second, it will bring into teaching a new cadre of knowledgeable, enthusiastic individuals, who are likely to bring with them new ways of looking at the classroom
experience. Third, it will emphasize the importance of having teachers know well the subjects they teach.

The alternate route to certification will also give traditional teacher education programs competition that could invigorate the entire profession.

Perhaps most important, the alternate route to certification will do away with the 40-year tradition of emergency certification in New Jersey. A common theme in the current dialogue on U.S. education is the need to professionalize teaching. As Linda Darling-Hammond put it in her Rand Corporation study of the crisis in teaching, "Until teaching becomes a more attractive career alternative, the problems of attracting and retaining talented teachers will undermine the success of other reforms intended to upgrade educational programs and curricula."26 And the key to making teaching more attractive, she concluded, is to make teaching more professional. Emily Feistritzer concurred. "If teaching is to become a true profession, it needs to act like one," she wrote.27 Yet teaching can never act like a profession without developing more rigorous entry and training requirements.

That is the goal in New Jersey. The revisions to the teacher certification code require that all traditional teacher education students in New Jersey also complete an academic major and that all teacher education programs cover the essential knowledge identified by the Boyer panel. The revised code requires that all candidates for certification—whether from the traditional or the alternate route—pass a test of subject-matter competency. The alternate route to certification will complement these changes in the code by attracting a new group of individuals to New Jersey classrooms and by eliminating the abuses of emergency certification.

7.8 Alternate routes to teacher certification
A dangerous trend

Doyle Watts

INTRODUCTION

The teaching profession has been plagued by the existence of a variety of substandard certificates including emergency, temporary and provisional. As undesirable as they are, these credentials are at least recognized as being inferior to standard teaching certificates. Persons issued substandard credentials are usually limited in the length of time they can teach and, if they wish to remain in the classroom, they have to meet standard certification requirements. The recent development of alternate routes to standard teacher certification poses a much greater threat to the quality of the teaching profession and our educational system. Unfortunately, it appears that the practice of issuing substandard credentials is being replaced with substandard preparation programs which lead to standard teaching certificates.

Persons who complete an alternate plan are issued the same professional certificate as teachers who are prepared through a standard program. This would not be of concern if alternate routes to teacher certification were of equal or superior quality. Regrettably, existing alternate certification programs are inferior. Indeed, alternate routes only appear to be short cuts for unqualified individuals to obtain teaching credentials and, thus, ill-prepared teachers are placed in charge of children’s education.

The commissioner of education in New Jersey described his state’s alternate route to certification in this fashion, “the reforms . . . were intended to replace the emergency system with a rigorous and legitimate alternate system . . .” (Cooperman, 1985, p. 24). Wonderful, if you believe that replacing a temporary substandard certificate with a substandard route to standard certification is an improvement. As Haberman (1985) pointed out, the New Jersey plan that Mr. Cooperman was praising requires less preservice practice for teacher candidates than that state mandates for cosmetologists, manicurists, barbers, private detectives or funeral directors. It does not appear, therefore, that New Jersey is leading the charge to achieve excellence in education through its alternate program for teacher preparation.

The requirements for alternate routes to teacher certification are inferior to those for standard preparation programs in at least one of four areas. First, applicants may be permitted to teach in subject fields where they have less academic preparation than is required for standard programs. In addition, alternate routes may require less college preparation in academic foundations. Also, teacher candidates in alternate programs may be required to have little or no pedagogical preparation. Finally, regulations for alternate preparation programs may not require participants to pass competency examinations and achieve performance standards which are mandatory for teacher trainees in standard preparation programs. An excellent illustration of how quality standards are lower for alternate routes to teacher certification is Texas House Bill 72. This legislation
specifically exempts those who progress through an alternate program for teacher certification from being required to take the competency examination in pedagogical knowledge which is required of all teacher candidates prepared through standard certification programs. It seems the Texas legislature has taken the peculiar position that a teacher prepared through an alternative program does not need to know how to teach.

WHY ALTERNATE PROGRAMS EXIST

The authority to establish standards and regulations for teacher preparation programs rests with state legislatures and state departments of education. Consequently, they must bear full responsibility for creating substandard credentialing processes which place the educational welfare of children in the hands of teachers who have not been properly prepared. The reasons given for opening these poorly defended back doors to teacher certification are not tenable.

One of the justifications frequently cited is the alleged shortage of teachers. But does a teacher shortage mean that there are fewer qualified teachers than there are available teaching positions; or does it indicate there is only a shortage of qualified teachers who are willing to accept available teaching positions in certain school systems? Although accurate data are difficult to obtain, it seems that colleges of education are continuing to prepare far more teachers than there are available teaching positions. For example, during the 1980–81 school year 3,257 teacher candidates graduated from Oklahoma colleges and universities but of that number only 1883 were employed in Oklahoma schools (Oklahoma State Department of Education, 1982). On the national level, there were 159,485 graduates completing teacher preparation in 1980 for the 71,425 open positions (NEA, 1981). During the 1980–81 school year, 140,639 graduates completed teacher preparation programs with only 76,550 available positions (NEA, 1983). Although these data are not current, they do indicate a continuing trend to prepare more teachers than there are available teaching positions. Consequently, it appears that, overall, vacant teaching positions are not due to a lack of qualified teachers but, instead, to a district’s inability to attract those teachers.

Why then, do teacher shortages exist in some areas? For what reasons are we unable to staff certain schools with properly prepared teachers? The reasons are unclear. However, Goodlad (1983) found that teachers leaving the profession cited excessive administrative requirements, lack of professional autonomy, poor parental support and the absence of a practitioner-client relationship between teacher and students as their principal reasons for deciding to resign. And, of course, poor salaries have been cited extensively as being a factor in creating teacher shortages.

It seems that large inner city districts are the ones experiencing the most difficulty in attracting qualified teachers. As a result, these systems are having to depend more and more upon teachers with limited preparation to staff their schools. In striving to solve the problem of teacher shortages, these systems and state departments of education would be well advised to direct their efforts toward the solution of conditions which keep qualified teachers out of these classrooms instead of attempting to unearth means by which standards can be circumvented and poorly prepared teachers placed in schools. Inner city school systems might be more successful in attracting and retaining qualified teachers if funds presently earmarked to import teachers from abroad and to provide superficial teacher training to unprepared adults were used to improve conditions which make the inner city schools an unattractive place for teachers to practice.

A second justification is the claim that pedagogical preparation is unnecessary and that any educated person can teach effectively. This is an odd notion. Other professions are not subjected to this kind of attack. Few would profess that knowledge and skills developed in medical school are unnecessary for the successful practice of medicine or that dental schools contribute nothing
worthwhile to the practice of dentistry. Yet, in the teaching profession, weak preparation programs are justified with the absurd assumption that teachers have no need of formal preparation in pedagogical knowledge and skills.

The belief that standard teacher preparation programs are somehow preventing outstanding individuals from entering the profession also exists. One hears the complaint that Socrates could not pass teachers competency examinations or meet present teacher certification requirements and, consequently, would not be permitted to teach in a modern American school. It is therefore concluded that present teacher certification standards are keeping potentially excellent teachers out of the classroom. But it is also true that Hippocrates would likely have trouble passing a modern medical examination and Plato would probably be unable to answer a majority of the questions on a current bar exam. However, in the case of medicine and law, this condition is not used as a justification to eliminate standards for entrance into those professions.

Also, those who favor substandard routes to teacher certification maintain that having a poorly qualified adult in the classroom is better than having no one there. But is a poor teacher better than no teacher? We must consider that extensive damage may be done to students through ignorance on the part of poorly trained teachers. In addition, the use of ill-prepared teachers encourages delays in seeking effective solutions to the causes of these shortages. Of all the professions, teaching seems to be the only one where a shortage of practitioners is solved by reducing the quality and duration of professional preparation. Understandably, the American Association of Colleges for Teacher Education’s Task Force on Certification has called for “a halt to the practice of admitting unqualified persons into the profession through emergency certification procedures or ‘alternatives’” (AACTE Task Force on Teacher Certification, 1984, p. 23).

HOW ALTERNATE PROGRAMS ARE ESTABLISHED

Unlike other professions, substandard credentials and short-cut routes to certification have not only been tolerated by the teaching profession but accepted by state departments of education and employing school districts as being legitimate. I know of no state that provides substandard credentials or allows substandard routes to standard credentials for the practice of medicine, law or pharmacy. Yet a great majority of the states provide ways a person may acquire a teaching credential through some short-cut strategy (Watts, 1982).

No distinctions are made in terms of salary, benefits, status, or professional authority and responsibility based on the type of preparation program the person completes. Those who progress through weak alternate certification procedures are granted the same professional rights and privileges as teachers who complete standard programs. Consequently, many less capable persons may be attracted to alternate preparation routes that are shorter and less demanding than standard programs. The big losers, of course, are students who receive inferior pedagogical services.

Unlike other practicing professionals who publicly display their professional licenses, teachers’ certificates are almost never publicly displayed but are, instead, filed away in personnel folders in central administrative offices. Neither parents nor students are informed concerning the type of certificate held by the practicing teacher or how it was acquired.

THE RESULTS OF ALTERNATE PROGRAMS

Although there is little empirical research information concerning the effects that teachers prepared through alternate programs are having on the teaching profession and the quality of our educational system, the impact is not likely to be favorable. Such investigations are needed now.
Long term, harmful effects on students are possible. Incompetent practice can have a damaging influence on the educational and psychological welfare of students. We take steps to ensure that the dentist who fills our child’s tooth has the proper training to accomplish that task. Anyone who practices as a dentist without such training would be subject to criminal charges. Yet we permit persons without proper training to practice as teachers of our children. The effects incompetent teachers have on our youth and society may be much more serious and destructive than permitting an ill-prepared person to fill a tooth.

Because of inadequate professional preparation, teachers may use inappropriate or ineffective pedagogical strategies and techniques resulting in students’ inferior academic achievement. The effects could be devastating. Consequently, many students will fail to achieve their potential because of their lack of essential knowledge and skills. Not so obvious but equally important is the negative impact that poor academic achievement can have on students’ attitudes, self-confidence and self-concept. Thus, we must take special care to ensure that those charged with the responsibility of delivering educational services to our youth have the necessary professional preparation to deliver those services in a competent fashion which incorporates much more than a simplistic notion that teaching is the delivery of facts and information.

The use of substandard routes to credentialing teachers also keeps teaching from progressing as a profession. When persons who have little or no professional training are issued credentials to teach, it is difficult to convince anyone that teaching is an important or difficult task. This incorrect perception inhibits the development of preparation programs comparable in scope and quality with those of other professions. Thus, the notion is perpetuated that most of a teacher's pedagogical training can be picked up on the job and that pedagogical knowledge and skills are not necessary anyway. Consequently, the progress of the profession is constantly stymied. In the long run, such stagnation will only hurt the children.

At a time when many schools of education are expanding their teacher preparation programs to five and six years, poorly designed alternate certification schemes are also springing up. If the trend continues and if alternate preparation programs continue to be inferior, in the near future, school systems in small cities and suburbs may be staffed with teachers who have completed extended teacher preparation programs while inner city districts are only able to attract as teachers persons who have much less professional training. As a result, the gap in the quality of education in urban and suburban districts will widen. Those students who need the most capable, best trained teachers will be served by weak, poorly prepared counterfeits.

CONCLUSION

If alternate routes to teacher certification actually meant a higher quality preparation system, then these programs would merit support. Unfortunately, they only appear to be a quick-fix scheme designed to place any adult, regardless of his/her professional preparation, in vacant classrooms. Consequently, they are another obstacle to efforts to advance the teaching profession and to achieve excellence in our educational system.

REFERENCES

The fact that schools of education could no longer rely on a captive body of aspiring teachers would expose them to the cleansing winds of competition.

Picture Gerard, a 28-year-old business consultant who majored in economics at Williams College and graduated with a 3.7 GPA. Gerard has been working for a consulting firm in Stamford, Connecticut, but is looking for a new, more fulfilling position. He has demonstrated strong interpersonal skills and work habits. In addition, though he didn’t major in math, he aced several calculus courses in college. Yet if Gerard were to apply through normal channels to teach math at a junior high school in the Hartford public school system, his application wouldn’t even be considered. Why? Because he isn’t a certified teacher.

Why shouldn’t a principal or a faculty hiring committee in the Hartford schools even be allowed to look at Gerard’s application, to judge his qualifications against those of other candidates? The assumption undergirding the contemporary approach to teacher certification is that public school hiring personnel are either unable or unwilling to gauge the quality of applicants. Our response has been to embrace a bureaucratic solution that handcuffs the capable and incapable alike and supposedly keeps weak teachers out of the classroom. As a result, having discouraged or turned away Gerard and hundreds like him, many large school systems resort to last-minute fill-ins who teach on emergency certificates.

This is not to suggest, even for a moment, that candidates with “real world” experience or high GPAs are necessarily qualified or equipped to become teachers or that professional preparation for teachers is unimportant. It is only to say that some potential applicants might be more effective teachers than the alternatives that are currently available to public schools.

The central premise underlying teacher certification is that—no matter what their qualifications are—anyone who has not completed the specified training is unsuited to enter a classroom and must be prohibited from applying for a job. Presumably, the danger is that, in a moment of weakness, a school official otherwise will mistakenly hire such an applicant rather than an appropriately trained teacher. It is essential to remember what we often seem to forget, which is that allowing someone to apply for a job is not the same as guaranteeing him employment. Making applicants eligible for a position simply permits an employer to hire them in the event that they are deemed superior to the existing alternatives. The argument against certification is not that unconventional applicants will be good teachers; it is only that they might be. If one believes this, case-by-case judgments are clearly more appropriate than an inflexible bureaucratic rule.

Imagine if colleges and universities refused to hire anyone who lacked a Ph.D. They would lose the talents and insights of “lay practitioners” like poet Maya Angelou, journalist William Raspberry, or former public officials such as Alan Simpson, Julian Bond, and Al Gore. The artists and writers “in residence” at dozens of public universities would fail to meet the criteria implicit in the public school certification model. Do we really believe that these universities are ill-serving their students by hiring people whom the public schools would consider unqualified?
COMPETITIVE CERTIFICATION

The theory behind certifying or licensing public school teachers is that this process elevates the profession by ensuring that aspiring teachers master a well-documented and broadly accepted body of knowledge and skills important to teaching. Supporters of teacher certification often make analogies to professions like law and medicine, where being an effective professional requires the acquisition of vast knowledge and skills. Licensure in these professions ensures at least minimal competency and boosts the public’s confidence in members of the profession.

The problem is that no comparable body of knowledge and skills exists in teaching. Debate rages over the merits of various pedagogical strategies, and even teacher educators and certification proponents have a hard time defining a clear set of concrete skills that makes for a good teacher. Yet most aspiring teachers are still forced to run a gauntlet of courses, requirements, and procedures created by accredited training programs that vary dramatically in quality.

This is not to deny that teacher education can provide valuable training. After all, one may think that journalism schools produce better journalists without requiring all journalists to complete a mandatory set of courses before seeking work in the profession. Instead, it is assumed that a candidate’s training is factored into the hiring process, along with considerations like aptitude, diligence, and energy.

Clearly some sort of screening process for aspiring teachers is essential; parents and the public rightly expect safeguards for those working with youngsters. What is needed is a competitive certification process that establishes key criteria for entry into the teaching profession; gives public schools greater freedom to hire and fire teachers; and treats teachers like professionals and their schools like professional institutions by allowing them to tailor professional development to meet the needs of teachers. Under such a model, aspiring teachers ought to be able to apply for a teaching job if they:

- Possess a B.A. or B.S. degree from a recognized college or university.
- Pass a test that demonstrates competency in knowledge or skills essential to what they seek to teach. The definition of “essential” knowledge or skills is obviously a loose one that can be interpreted in myriad ways and rightly should be different for those wishing to teach younger children or older students. The key point is to demand that teachers at least have an appropriate academic knowledge of the material they will be teaching.
- Pass a rigorous criminal background check. States conduct such checks now, but they tend to be compromised by the state’s need to engage simultaneously in related certification paperwork.

Beyond these minimal qualifications, the competitive approach presumes that preparation and training are not only desirable but also essential, as is true in other professions where subtle skills and interpersonal dynamics are essential to effective performance. The questions are where to obtain this training and who should pay for it. Contemporary teacher preparation imposes nearly all of the costs on candidates by forcing them into a system of training that removes key incentives for quality and relevance in teacher preparation. The competitive model instead treats teachers as autonomous professionals able to make informed decisions about developing their skills and expertise. In short, the competitive model would substitute meaningful professional development for what is essentially a guild system funded by levying a significant tuition-based tax on aspiring teachers before permitting them to enter the profession.
THE ASSUMPTIONS OF CERTIFICATION

Over the years, an array of studies has sought to determine whether certified teachers serve students more effectively than uncertified teachers. There are two problems with this line of work. First, the methodological wrangling has often obscured the larger questions and the central assumptions of the certification model. Second, the case for certification is thin whether or not certified teachers boost student achievement more than their uncertified peers. The issue is not whether teacher education improves the performance of graduates, but whether we ought to—as best we are able—bar from teaching those who have not completed an approved preparatory program. Certification systems deny school administrators the ability to take their context or the promise of a particular applicant into account when hiring. Even if certified teachers are generally more effective than uncertified teachers, such a policy only makes sense if we believe that uncertified applicants are uniformly incompetent to teach or that school administrators cannot be trusted to assess their competence.

The allure of certification rests on three implicit assumptions. They are the beliefs that: (1) the training one receives while getting certified is so useful that the uncertified will be relatively ill-prepared; (2) certification weeds out unsuitable candidates; and (3) certification makes teaching more "professional" and therefore a more attractive career. However, each of these presumptions is problematic in the case of teacher certification.

As a general principle, certification is most effective when the licensing body ensures that aspiring professionals have mastered essential skills or knowledge and denies a license to inadequate performers. Licensure is most essential when a professional’s tasks are critical and when clients may have trouble assessing a provider’s qualifications. For instance, licensure is considered particularly appropriate for engineers, doctors, and attorneys because those who design bridges, tend us when we are ill, or defend our rights all perform tasks essential to our well-being and are frequently charged with aiding us at our most vulnerable. Moreover, it can be difficult for members of the public to know whether a bridge is properly designed, whether a doctor is performing appropriately, or whether an attorney is knowledgeable in the law. Licensing is not an assurance that these professionals are talented practitioners, but it does ensure that they have demonstrated an established degree of professional knowledge.

Educators are also charged with a crucial task. However, the oversight challenge is very different in education, where we have not established a specific, measurable body of skills or knowledge that teachers must master. Educational "experts" themselves argue that teaching is so complex that it can be difficult to judge a good teacher outside of a specific classroom context. This makes it difficult, if not impossible, to determine abstractly which aspirants possess satisfactory “teaching skills.” Meanwhile, there is widespread agreement that colleagues, supervisors, and families have at least a proximate ability to gauge whether a teacher is effective. Given these circumstances, it is unclear how standardized licensing helps to safeguard teacher quality.

Such a conclusion does not require refuting the claims of teacher educators or the supporters of certification. It actually follows if one simply accepts their claims. Professional educators themselves have thus far been unable to explain in any concrete sense what makes a teacher competent or what teachers need to know and be able to do.

Consider the widely praised standards that the National Board for Professional Teaching Standards (NBPTS) has painstakingly constructed in 27 distinct fields, standards that certification’s proponents have hailed as a breakthrough in quality control. The area where the NBPTS sought to have the easiest time creating straightforward standards is high school math and science teaching, where there is widespread consensus as to what teachers are supposed to do. Even in these areas, however, the NBPTS’s “exemplary” standards are so broad and vague as to make concrete judgments of competence nearly impossible. For instance, to receive National Board certification to teach high-school math, teachers are to demonstrate mastery of
11 standards, including: commitment to students and their learning, the art of teaching, reflection and growth, and reasoning and thinking mathematically. The board tries to clarify these standards by explaining, for instance, that “commitment” is interpreted as meaning that “accomplished mathematics teachers value and acknowledge the individuality and worth of each student, believe that all students can learn,” and so on. Mastering the “art of teaching” is taken to mean that teachers “stimulate and facilitate student learning by using a wide range of formats and procedures.” While these are certainly admirable sentiments, nowhere in the National Board’s rarified standards is it clear how we are to gauge just what constitutes “competence” in these tasks. The result, unsurprisingly, is that the board has been assailed for the capricious way in which the standards are being interpreted and applied. Despite the best of intentions in the drafting of the INTASC standards, which Mary Diez discusses, a cursory read makes clear that they are plagued by the same ambiguities evident in the NBPTS standards.

For another prominent example, consider education professors Gerald Grant and Christine E. Murray’s award-winning 1999 Harvard University Press book, Teaching in America. They identify five “essential [teaching] acts” that can be analyzed and taught: listening with care; motivating the student; modeling caring by hearing and responding to the pain of others, and by creating a sense of security in their classrooms; evaluating by clarifying, coaching, advising, and deciding on an appropriate challenge for this boy or that girl; and reflecting and renewing. How one is to teach these five “essential acts,” much less determine whether a teacher has satisfactorily mastered them, are questions that Grant and Murray never address.

If clear standards of professional competence do not exist, we typically (and appropriately) hesitate to prohibit some individuals from practicing a profession. This is not to say that we think incompetence is acceptable in such a profession—only that we recognize licensing as an ineffective and potentially pernicious way to control quality. While licensure could protect community members (including children) from exposure to “bad” entrepreneurs or journalists, we do not prohibit some people from seeking to start businesses or work for a newspaper. Instead, we trust that potential investors or employers are the best judges of who ought to be supported or hired. If an aspiring writer or entrepreneur is unsuccessful, we trust that they will eventually be persuaded to find a line of work for which they are better suited. This free-flowing process fosters diversity and ensures that unconventional workers are given a chance to succeed.

Even in professions with clear knowledge- or performance-based benchmarks for certification, as in law or medicine, licensure is useful primarily as a way of establishing minimal competence. A medical or a law license is not imagined to ensure competence in ambiguous, subtle skills like comforting a patient or swaying a jury—skills analogous to the interpersonal relations thought crucial to teaching. Basing certification on such traits is difficult, because we may disagree about what they entail or how they can be assessed devoid of context. The skills that teacher educators deem most important—listening, caring, motivating—are not susceptible to standardized quality control. Emphasis on these qualities is the norm in professions like marketing, journalism, consulting, or policymaking, where a subtle blend of people skills, knowledge, and relevant expertise is required. In professions like these, where there are a number of ways for practitioners to excel but where it is difficult to know in advance how any particular practitioner will perform, the most sensible way to find talent is to allow aspirants to seek work and to permit employers to screen on a variety of criteria—such as education, experience, and references.

**A DUBIOUS SCREEN**

While certification can serve to screen out aspirants who fail to meet a minimal performance standard, our current system is not designed to do so. Generally speaking, schools of education
are not selective, flunk out few if any students for inadequate performance, and see that many of
their teacher education graduates receive teacher licenses. The licensing exams are simple, and
standards for passage are generally so low that the Education Trust concluded they exclude only
the “weakest of the weak” from classrooms.

More than 1,300 institutions provide the training required for licensure. While defenders of the
current approach to certification often focus on the certification programs at elite institutions, the
top 25 education schools train less than 5 percent of the roughly 200,000 new graduates that
teacher programs produce each year. It is the regional colleges, such as Illinois State University,
Cal State–Hayward, and Southwest Texas State University—not the Stanfords and the Ohio
States—that train and license the vast majority of teachers. The value of certification turns not on
the quality of elite programs but on that of regional colleges.

Teacher-preparation programs neither screen out nor weed out weak candidates. Even at elite
schools, such as UCLA or the University of North Carolina, where admissions rates are about
5 percent for medical school and 25 percent for law school, the M.Ed. programs (which include
those seeking postgraduate training for teacher certification) accept more than half of their appli-
cants. Moreover, education-school officials often make it clear that they do not see their mission
as weeding out students during their course of study. Notes one such official, “We’re here to
develop teachers, not to screen people out. For the most part, everyone who enters the program
is going to complete it, unless they decide that teaching’s not for them.”

THE COSTS OF CERTIFICATION

Especially for anyone who didn’t complete a teacher-training program as an undergraduate, the
costs of certification can be significant. It is not unusual for postgraduate teacher training pro-
grams to require a full-time commitment of 16 or even 24 months or a part-time commitment that
can stretch to three years or more. The cost of training and the loss of salary due to time spent out
of the workforce can easily reduce a teacher’s real compensation during her first five years by
25 percent or more.

These barriers make other professions relatively more attractive, so that potentially talented
teachers who are unsure about their interest are less likely to try teaching. Whereas candidates
can readily try journalism or consulting or marketing for a year, they must make an extensive
commitment before they can try public school teaching. The result is that many who might make
fine teachers never enter the profession. There is disturbing evidence that certification may
especially dissuade accomplished minority candidates—who have a number of attractive career
options and who are often less well situated to absorb the costs of teacher preparation—from
entering teaching.

This would pose no real problem if we were blessed with a surplus of good teachers. In such a
case, we might scoff “good riddance” to those dissuaded from teaching. However, we have a
desperate need for competent teachers. Moreover, rather than a lack of commitment to teaching,
a reluctance to pursue certification may indicate that individuals have attractive alternatives. It is
the most talented and hardest working individuals who have the most career options and who
sacrifice the most by entering a profession where compensation is unlinked to performance and
where opportunities for advancement are few. They may wish to teach but be unwilling to forgo
work for a year, sit through poorly regarded courses, or jump through procedural hurdles. It is
candidates with fewer attractive options who will find the tedious but intellectually undemanding
requirements of certification less problematic. In fact, by suppressing the supply of teachers,
certification provides teachers with enhanced job security. Coupled with a compensation scale
that rewards seniority rather than performance, certification may well make the profession more
attractive to graduates seeking a less demanding line of work. In this way, certification can
actually harm the public’s perception of teaching as a profession—the very opposite of what certification proponents wish to do.

CREATIVE DESTRUCTION

In a world without certification as we know it, districts and schools would have more flexibility to ensure that their new teachers are prepared, inducted, and supervised in a manner appropriate to the challenges at hand. Because aspiring teachers would no longer have to attend formal teacher-preparation programs in order to teach, they would be free to make professional decisions about training in the same manner as business school or journalism school students. Weaker teacher-preparation programs would likely fall by the wayside. The fact that schools of education could no longer rely on a captive body of aspiring teachers would expose them to the cleansing winds of competition. Schools would have to contribute value—by providing teacher training, services, or research that created demand and attracted support—or face significant cutbacks. Teacher-preparation programs would find it in their own self-interest to ensure that their graduates were knowledgeable and skilled, as this would help graduates to win desirable jobs amid increased competition, making preparatory institutions more attractive.

Under a competitive certification system, little is likely to change in many of our high-performing suburban districts, where officials are inundated with applicants and are unlikely to tamper with a formula that is “working.” In such districts, except in rare cases, we would expect that administrators would continue to cherry-pick from the nation’s top teacher-education graduates. It is in the less desirable and more troubled systems, the nation’s urban and rural school districts, that administrators currently have tremendous difficulty finding sufficient numbers of certified teachers. This is doubly true in the areas of math and science education. It is in these districts and subjects, where critics have fretted about the numbers of long-term substitutes and “burned out” veterans, where the wave of new teachers will most likely be recruited and welcomed. While many of the resultant applicants will no doubt be deemed unprepared or unsuited for the jobs they pursue, there are few urban or rural principals who would not welcome the chance to pick and choose from their ranks.

Critics may fear that the elimination of licensure requirements will mean the end of teacher preparation and professional development. Such concern is unfounded. First, allowing uncertified individuals to become teachers does not mean that they must be viewed as “completed” professionals. Such a mindset is one of the vestiges of our current system, which is erected on a premise that all teachers are certified and therefore competent. Here, a better model might be medicine or law, where entering professionals begin their career with a trial period (serving as a hospital resident or as a junior partner in a law firm, for instance) during which their full panoply of skills is developed and monitored. Beginning teachers might serve on a probationary basis, receiving substantial monitoring and counseling. However, legal and contractual language ought to make it much simpler to terminate ineffective teachers or to mandate that they engage in support activities designed to improve their performance.

Second, moving to competitive certification does not mean doing away with professional teacher-education programs. Many applicants attend journalism school or business school, even though such training is not officially required, because it may make graduates more effective and can help them find better employment more readily. Likewise, aspiring teachers would presumably continue to attend those teacher-training programs thought to enhance their employability. This change would introduce some much-needed market pressure in this area, as schools would be forced to compete for students based on the usefulness of their course offerings.

Giving districts more leeway to hire promising candidates does not mean they will always make good decisions. Some ineffective teachers will inevitably continue to be hired. However, if entry to
the profession is eased, it is appropriate that exit be eased as well. If administrators are to have more leeway to make hiring decisions, they also must be given more leeway to fire—and they must be held accountable for both sets of decisions.

At the end of the day, the individuals best equipped to assess the qualifications of prospective teachers are the principals who will be responsible for them. These same principals ought to have the strongest incentive to see that teachers are effective. If we believe that the administrators charged with managing and supervising schools either are unequipped to evaluate prospective teachers or are unwilling to do so, teacher certification will not suffice to protect our children from such profound systemic dysfunction. If we trust administrators, then certification is unnecessary and entails significant costs. If we don’t trust administrators, let us address that issue directly and not rely on the hollow promise of flimsy parchment barriers. Regardless, it is past time to fully acknowledge the nuanced, multifaceted, and professional nature of teaching and to move beyond a system that restricts professional entry with procedural barriers characterized by ambiguity that are the result of an inability to clearly define the skills, knowledge, or training essential to good teaching.
I think it is time for those of us in teacher education to consider ignoring the educational policy makers that are undermining our efforts to develop thoughtful, autonomous, and effective teachers. Current federal teaching and learning policy is more likely to undermine teacher quality than improve it (Cochran-Smith, 2002; Darling-Hammond & Youngs, 2002). Federal and state mandates on standards and testing are narrowing the curriculum and are focused on the lowest levels of learning (Elmore & Rothman, 1999; Hillocks, 2002; Paris & Urdan, 2000). Federal efforts to establish so-called “proven” programs as the mandated curriculum (Allington & Nowak, 2004) work against filling classrooms with powerful teaching provided by engaged, expert teachers. In addition, each of these policies flies in the face of what the research says about effective teaching and learning.

I suggest that it is a rare policy maker that shares my understandings of how we might best foster expertise and personal professional accountability in teachers. It is even rarer to find a policy maker who cares one whit about what the research says (unless it supports personal views or the findings are reflected in polling data). Federal and state policy makers routinely ignore the research evidence on improving teaching and learning and offer, instead, grand schemes that simply cannot be expected to achieve the meritorious goals suggested in the bipartisan advocacy for the federalization of teaching and teacher education (Allington, 1999, 2001, 2002).

I have watched as federal and state policies concerning improved reading instruction have been enacted across the nation—policies that often have little base in research and little credibility among those who work in the complex organizations we call schools. I have watched as educational research has been savaged and redefined as a narrow set of quantitative schemes. I have watched as the two states where I have recently worked (Florida and New York) have crafted tighter and tighter regulations for teacher education, often with the support of the National Council for Accreditation of Teacher Education (NCATE), while at the same time deregulating entry into the profession for those who have never set foot in a college of education.

It was during my first NCATE/Florida Department of Education accreditation review, as I watched faculty expend enormous time and effort sitting in meetings to learn the process developing matrices, targeted assessments, standardized course outlines, and such, the college expended substantial funds for consultants and lots of administrator and support staff time, that I began to wonder if the irony of the process of earning accreditation had occurred to others.

As far as I can tell, the whole point to accreditation, as now conceived by NCATE and state education agencies, is to homogenize teacher preparation, usually in the direction of the lowest common denominator. We are pressed to accept statewide course syllabi, assignments, and assessments, even statewide college textbook adoptions. Our students are pressed to develop standardized electronic portfolios (seems oxymoronic to me), to prepare to take standardized
group achievement tests of professional and content knowledge, and to elect as their under-
graduate majors one of five or six core disciplines (but child development, linguistics, and sociol-ogy are not among those majors suggested).

Art Wise (1979), now NCATE executive director, wrote some years ago about “goal reduction”
as one outcome of bureaucratic rationalization and centralization. Goal reduction evolves as an
unintended effect of rationalizing education. Setting goals results in minimal expectations and
the exclusion of some goals (those on which not everyone would agree or those not amenable to
group standardized testing). Preeminence is given to goals that seem to address pressing social
problems versus individual goals (national economy vs. individual fulfillment). He concluded that

in the drive to make educational institutions accountable, goals have become narrow, selec-
tive, and minimal. That which is measurable is preferred to that which is immeasurable.

(p. 59)

I would suggest that he described what is happening in teacher education today.

My response, the only one that seems viable to me, in fact, is that we begin a campaign to
ignore state and federal bureaucrats and policy makers who would dumb down our work. I think
teacher educators need to seriously consider what benefits to them (or their students), if any, are
actually accrued by earning accreditation for their programs. In other words, I am arguing that we
disassociate our programs, our institutions, and ourselves from the whole accreditation process.
We would do well to also consider disassociating ourselves from the teacher credentialing pro-
cess. I am convinced that we must document that the courses and experiences offered in our
teacher education programs do matter. Unfortunately, the teacher educator’s role in credentialing
has become more a matter of assuring the right course distribution than documenting graduates’
expertise and effectiveness. All those completed matrices may look official but they are, funda-
mentally, bureaucratic ruses rather than convincing evidence of competence.

BENEFITS OF IGNORING STATE AND FEDERAL ACCREDITATION
AND CREDENTIALING MANDATES

I see potential benefits from electing to ignore state and federal policies regarding accreditation
and credentialing.

A renewed focus on what is important in teacher development

Is there anyone who has been through an NCATE/Department of Education review who cannot
document the trivialization of teacher education (Johnson et al., in press)? How many thousands
of hours are taken from other activities to create mindless matrices of standards from state
education agencies, the NCATE, and one or more specialized professional associations (e.g.
National Council of Teachers of English, Association for Childhood Education International,
International Reading Association, National Science Teachers Association)? Or to attempt “to
document,” that is, assess, whether students have acquired the appropriate “dispositions”
required to be credentialed? And what research suggests that only certain dispositions are found
in effective teachers? Or that anyone can reliably assess a disposition?

What evidence demonstrates that accredited teacher education programs more often prepare
effective teachers than nonaccredited programs (about half of the teacher education programs in
the United States are not accredited by the NCATE or the Teacher Education Accreditation
Council)? We do know that graduates of traditional (but not necessarily NCATE-accredited)
teacher education programs differ on several qualities important to both their employers and their
students (Darling-Hammond & Youngs, 2002; Ferguson, 1991; Hoffman & Roller, 2001). But there is no convincing evidence that national program accreditation reliably predicts the development of more effective teachers.

Perhaps this lack of research is irrelevant. My primary concern is that by participating in state and national accreditation processes, we are eliminating our best opportunity to develop programs that produce effective teachers even more reliably. Given the federal fervor surrounding “scientific evidence” as the basis for educational decision making, I have taken the stance that without substantially better evidence that a national, corporate model of accreditation is an effective option, we have an obligation to continue to explore just what sorts of courses and experiences develop the teachers this nation needs.

Deciding to pass on the accreditation of our teacher education programs produces that opportunity to experiment with “homegrown” teacher education plans. It is, in my view, experimentation that is the engine that drives improvement. It is exploration, not mindless adherence to mandates, that offers us the best option for improving teacher education. Personal professional accountability should be the standard for both teachers and teacher educators. But such accountability rarely arises when we simply do what we are told to do. If I am given the syllabus, the textbook requirement, and a set of assessments that I must complete for each of my teacher education students, why would I feel accountable if few of them actually become effective teachers?

Perhaps we would be satisfied to let the marketplace determine our success under this model. That is, do our candidates get hired and are school districts satisfied with their performance? The lack of research support for the accreditation model suggests that gaining professional employment under a marketplace model would differ little from what already exists. Schools would continue to hire graduates of institutions known to reliably produce effective teachers, accredited or not.

We should work to capture accreditation process money and time for use in far more frequently and rigorously evaluating just what sort of teachers we are preparing. The time, energy, and money that are now spent preparing for and passing through an accreditation process could be used, instead, to fund and staff ongoing studies of the effects of our work. The costs of pursuing NCATE accreditation have been estimated to fall in the US$100,000 to US$800,000 range, without accounting for faculty time spent preparing all those standard syllabi and matrices of accomplishments (Johnson et al., in press). That is a lot of money and faculty time buyout to do research to assist us in deciding what sorts of things really matter in the preparation of effective teachers. And because we would be using internal funding (which means we should not have to turn over that 50 percent of a grant now assigned to indirect costs and overhead), we could employ a wide range of research methods, not just those now deemed “fundable” by federal research agencies.

Imagine the sort of studies that might be done with the resources allocated to an accreditation review. In my experience, that would mean a couple of full-time consultants for a period of 3 years or more, a secretary position, several graduate research assistants, a project director (using the administrative line usually assigned to head the accreditation process), and substantial release time and “borrowed” time from faculty members, including many from outside the college of education (e.g. art, music, agriculture, history, and health and human development departments). An interdisciplinary research team with financial and faculty resources focused on improving our current efforts. I can imagine any number of creative and powerful studies that might be accomplished with such support. It is not that such resources are not available but rather, that those resources are currently allocated to the accreditation process. Capturing those resources to support a continuous program of research on teacher education is, in my view, more likely to improve our teacher preparation than if we elect to simply continue complying with dumbed-down bureaucratic demands.

What I am suggesting is that there is a professional imperative to provide good, local evidence
of effects of teacher preparation. We cannot simply continue to comply with norms and processes formulated by state and federal bureaucrats and policy makers and consider ourselves professional. In fact, compliance suggests that we are attempting to abdicate responsibility to study what we do and the effect our work has on our students. What I am arguing for is greater personal professional accountability among teacher educators and better evidence of the impact of our efforts on those who would be teachers.

AND THEN, OF COURSE, THERE ARE THOSE CONCERNS

But our graduates won’t be certified!

Perhaps so. However, I do not see the problem with that. Most states offer a variety of avenues to become credentialed and these avenues are not nearly as rigorous as the traditional teacher education program process. Consider the modest demands placed on those in the Teach for America, Troops to Teachers, and other “fast-track” credentialing options. Consider the recent New York State option that allows anyone with a baccalaureate degree to work for 40 days as a teacher and, with college supervision, earn licensure. Or the similar recent legislation in Texas that literally bars requiring a teacher credential in hiring a teacher. I fully expect that such options will be expanded as the need for teachers grows in the coming decade. My advice: Counsel students to use the alternative routes and leave credentialing as a matter to be negotiated between the state education agency and the student.

We can use the federal policy makers’ fascination with the “marketplace” (Podgursky, 2004) model—hire anyone and fire those that do not work out—to our advantage, all the while producing research that demonstrates the value of our work. Teachers are already hired more by where they came from (which institution of higher education) than by whether they graduated from an accredited program. Producing substantive evidence of our graduates’ proficiencies and expertise will but enhance the attractiveness of our graduates in the marketplace. Of course there is an associated risk—that we will not be able to produce credible positive evidence of our program effects. But that is a risk I am willing to take.

Won’t this deprofessionalize teaching?

Others worry that my stance suggests that teaching is not a profession and that disassociating ourselves from the accreditation process will undermine efforts to bolster the professionalism of teachers and of teacher education. Lots of folks use medicine and medical education as a model to pursue. But the idealized version of medical professional education seems more than a bit overblown. The research on medical practice suggests that evidence, as in experimental studies, might be a primary factor in only about 20 percent of all medical decisions doctors make (Hitt, 2001). Furthermore, as Frohlich (2003) noted in his editorial in the New England Journal of Medicine, a basic problem with experimental medical intervention studies is that they are at best a proxy for the care provided to individual patients by their own physicians (a point largely unconsidered in experimental education research). Frohlich observed that although researchers focus on responses at the population level in order to develop therapeutic guidelines, health care providers must deal with the specific relationship between the physician and the patient. This relationship is where the therapeutic tire meets the road, and there is no place for absolute or categorical answers. Population-based studies of therapies help point the way but are not analogous to the care of individual patients.

(p. 640)
Beyond the hyperbole about the merits of medical education and its role in professional licensure as a model for the education profession, there is the problem of scale. With only 85 medical schools in the United States, the process of monitoring medical education is far less complex than the problem of monitoring nearly 1,300 teacher education programs and their graduates (Johnson et al., in press). And then there is the problem of the length of time it takes to become a physician compared to the time it takes to become a teacher.

We participate in the teacher credentialing process largely as dupes. Someone else sets the criteria, creates the budgets, monitors the outcomes, and tells us what else must be done or what must be done differently. We endure the criticisms that our graduates are underprepared, even though they have met all the state and federal requirements and were educated within the system those policy makers developed and mandated. It is my contention that the additional degrees of autonomy my proposal provides would stimulate better teacher preparation programs. Taking on these responsibilities would enhance the professionalism of teacher educators and teachers, especially if we involve teachers as something other than experimental subjects in the research we do on our programs.

The college of education would go out of business if we don’t offer a credential

Perhaps, but only if we (a) fail to produce effective teachers and (b) fail to develop convincing evidence of our graduates’ expertise and effectiveness. In either scenario, getting out of the teacher education business might not be a bad idea.

But following the arguments above, I suggest that the sheer demand for teachers will likely ensure the life of colleges of education. Continued employment of our graduates is all but ensured given the professional and general population demographics. In addition, most school-based educators are products of colleges of education and seem largely skeptical of the “y’all come into teaching” craze that accompanies a marketplace mindset. However, the proof will have to be the effectiveness of graduates.

I am willing to leave credentialing wholly up to someone else. Perhaps the teacher unions would be the most appropriate credentialing agency, because it is their members who have the most to gain or lose when ineffective teachers are credentialed. Perhaps local school districts should have the power to credential candidates (they already have the power of granting tenure in most states). Again, local education agencies have more at stake than state or federal agencies (or colleges of education under the existing schemes) in ensuring that only the effective candidates are credentialed. I am convinced that teacher educators should focus more on developing and evaluating the effects of teacher education programs and less on attempting to ensure that program participants will be credentialed by some other agency or organization.

In any event, given that the less cumbersome, alternative routes to obtaining a credential are fast expanding, colleges of education may soon lose students and faculty to alternate route providers. Whether we like it or not, there will be an intensifying pressure on colleges of education to prove their worth. But how do we prove our worth? We can continue to be hindered by participating in the accreditation and credentialing sham or begin the harder work of providing clear evidence of the effects of our efforts. Unfortunately, I see no way to do both.

Commentaries
49 Teaching as a profession
A bridge too far?

Edward Crowe
The Bench Group LLC

For George Bernard Shaw, “all professions are conspiracies against the laity.” The history of teaching in the U.S. is the story of a struggle for professional status. For teacher preparation, it is a quest for respect as a form of professional education. This essay will argue that teaching is not yet a profession. It will suggest that teaching and by extension, teacher preparation have not taken the key steps by which occupations attain professional status.

To say that teaching is not yet a profession—and to argue that teacher preparation is not a form of professional education—is emphatically not to make the case that our children and schools do not need or deserve the benefits of professional status for teachers and teacher educators. The struggle to improve teaching and learning in the United States would be helped immeasurably if teaching were to become a true profession.

BECOMING A PROFESSION

Professions have certain characteristics. Professions develop and maintain consensus around a set of values that shape core activities including who enters, how they are trained, how they practice, how they are regulated, and how they defend themselves. Entry standards are established and enforced by the profession through regulatory bodies such as licensing boards. For this to happen, governments must accept the norms of the profession itself with regard to which individuals “deserve” entry. Those who seek entrance must perceive sufficient returns to justify the costs. These returns to professionalization include status, authority, and earnings (Kleiner, 2000).

Acquiring professional status is a struggle. Those who seek to transform their field into a profession must act together to create and enforce consensus about training and working practices. They must find ways to link education, accreditation, and licensure so that all three processes are driven by similar values and desired outcomes. This is a steep hill to climb. This chapter considers professionalization from several perspectives. Economists focus on the costs and benefits. Sociologists study the process of acquiring professional status, and its implications. Both perspectives shed light on the increasingly difficult battle facing teaching and teacher preparation.

LEGITIMACY AS THE BASIS FOR PROFESSIONAL STATUS

Successful professions function as communities (Begun & Lippincott, 1993, p. 30). Members are “bonded to each other by virtue of the similar education and training they
receive and the type of work they do” (p. 31). This makes professions different from occupations. Occupations acquire professional status through a complex process that entails a struggle for unity. Out of this contest, a professional community arises with shared norms, training, working practices, and regulatory mechanisms. In the wider world, there is a struggle with potential competitors, with purchasers of goods and services, and with agencies of government (legislatures, board and commissions, the courts). When this community is strong enough, the same values can be found in training programs, accreditation and approval processes, licensure policies, and professional practice. This results in coherence, unifies the profession, sets it apart from others, and provides a means of defense against “incursions” into one or more realms of the professional community. These strengths are economic and social assets (Begun & Lippincott, 1993; Starr, 1982).

Wilson and Tamir (this volume) describe the struggle for legitimacy in teaching and teacher education as “lively discussions” that often pit the “teacher establishment” against its critics. The jurisdictional challenges they portray are incursions into the “turf” of would-be professions. They adopt Bourdieu’s concept of a “social field” to examine the present-day role of teaching as a profession. While Bourdieu argues that the social field is a space where individuals and groups both work and struggle for power, economists have a different take. For them, professionalization is fundamentally about economic power and returns—who pays the costs and who reaps the benefits (Stigler, 1971). Thus economists would say that professions are economic constructs, with measurable benefits and costs both inside and outside the field.

The regulation of occupations by the state is a quintessential case of professionalization as an economic process (Kleiner, 2000). For sociologists, professions are political communities and scientific constructs, especially in the health professions where the political and social power of the profession rest on claims of scientific knowledge (Begun & Lippincott, 1993; Starr, 1982). The social field concept overlaps with economics and the sociology of occupations in that the social field is one part of the economic and sociological apparatus of professions. Economists and other scholars of the professions would claim that the internal social field—whatever its value to “residents”—only matters if it confers economic benefits on members and is accepted as a legitimate space by the wider world of regulators, consumers, and potential competitors.

The long course of teaching’s quest for status in the U.S. is about the twists and turns of efforts to define a field, create and maintain boundaries, and use education, accreditation, and licensure as components of professionalization. Sedlak (this volume) makes clear how these efforts have failed: “Everyone in this story has had interests to advance, careers to create, enhance, and protect.” Those in the field, and many outside it, continue to have “deep and enduring differences of perspective” (Sedlak, this volume).

Professional legitimacy implies acceptance by others. It gives the profession influence with “outsiders” such as the public and government. In health care, legitimacy is built from a scientific knowledge base, and supported by successful diagnosis and treatment of disease. Complexity of the knowledge base is a source of legitimacy (Begun & Lippincott, 1993). But if “complexity is not accompanied by results,” legitimacy is undercut by skepticism about the profession’s claims (Begun & Lippincott, p. 65). Here, then, is an important point of departure between teaching and the recognized professions. The knowledge base for teaching may be complex, but there is little credible evidence that links claims of expertise to teaching or learning results (Cochran-Smith & Zeichner, 2005). The jurisdictional challenges described by all three chapters concern legitimacy. The robustness of these battles and the inability to resolve them means that teaching and teacher education have failed to establish and
CREDENTIALING

Education, accreditation, and licensure are the components of credentialing. Credentialing is an indispensable source of professional legitimacy. The rigor and consistency of training provided to members of the professional community, particularly when that training claims a basis in scientific knowledge, helps to confer professional status on those who complete training. It is particularly persuasive when all members of the profession experience the same preparation regimen. Credentialing as a source of professional legitimacy also includes the receipt of degrees or certificates by individual members of the profession, licensure by the state, and accreditation of education programs by some external organization. Thus, credentialing involves three sets of “organized stakeholders—education sites, accreditation agencies, and government institutions” (Begun & Lippincott, p. 59).

The intersection of these interests—and their unity of purpose—is clearest in the health professions (Starr, 1982). Medical education is the classic example. Following the Flexner Report and other social forces (Brown, 1979; Cox & Irby, 2006; Flexner, 1910, 1940; Starr, 1982), U.S. medical schools standardized their training programs. Teacher education programs have not. Large-scale studies of “pathways” into teaching through various preparation routes have found more variation within pathways than between them (Boyd et al., 2006). Teacher training programs can be so different from each other that a leading scholar recently claimed, “there is no such thing as teacher education” (Shulman, 2006).

Sedlak (this volume) makes the point that, from the beginning of teaching as an occupation, significant pressures to strengthen credentialing and tie its key elements together (especially education and licensure) generally came from outside the field—except in the South where the preservation of racial separation was an important function of the education system. Later, the “teacher education establishment” (to use Wilson’s and Tamir’s phrase) was attacked from within the academy mostly by discipline-based academics. These events took place well into the 1960s—and, one can argue, the challenges continue today. Sedlak’s “loosely-coupled professional education enterprise” is Wilson and Tamir’s “orthodoxy.” From the perspective of real professions, however, being “loosely-coupled” is to fail at professionalization.

Imig and Imig (this volume) see teacher preparation at the receiving end of policy makers’ attempts to impose standards. However, for professions, the relationship goes in the other direction: credentialing is a means whereby a profession sets and enforces standards through influence over policy makers. It is my contention that many of the external policy pressures on teacher education over the years have resulted from the refusal of teacher educators to set standards or to enforce the few standards that did exist (Wilson and Tamir, this volume). There is no common set of values, collectively shared, and this is reflected in the existence of multiple credentialing entities for teaching and teacher preparation programs. As Begun and Lippincott note, successful credentialing involves three sets of “organized stakeholders” (p. 59) with unity of purpose (Starr, p. 115).

The third leg of credentialing is the system of training and education that produces members who are socialized into a set of common attitudes and values. Here, Wilson and Tamir document thoroughly the almost systematic absence of shared values, ideas, training methods, and outcomes. For Wilson and Tamir, arguments over the quality of teacher
preparation are tied to the “commingling of science and politics” (p. 25). They describe a “political battle for control over the teacher education field” (p. 26), which includes preparation, regulation, and research about teaching and learning. Even a casual reader of the professional press—Education Week, Education Next, or the Journal of Teacher Education—witnesses the sound and fury of these arguments. From the perspective of scholarship on the professions, however, there is no teacher education “field.” The absence of internal cohesion, the weak knowledge base, and the multiple “pathways” sanctioned by regulators (and increasingly by universities), suggest that the field as a concept in teacher education is so abstract as to lack meaning.

THE ROLE OF SCIENTIFIC KNOWLEDGE

Scientific knowledge is an essential foundation for professional status in the health professions. The claim to have and use scientific knowledge enables one group (e.g. traditional medicine) to control incursions by others (like alternative medicine), especially when the use of this knowledge can be shown to have beneficial results (Begun & Lippincott, 1993; Starr, 1982).

Wilson and Tamir describe the critics’ belief that there is a complete absence of scientific knowledge from teaching and teacher preparation. Yet we now have increasingly sophisticated scientific knowledge about teaching and learning (e.g. National Research Council, 1999, 2005; National Reading Panel, 2000; Halpern, 2003; Halpern & Hakel, 2003). What we do not have yet is the systematic application of science to teaching, or to the process of learning how to teach.

This may be because important segments of the teaching and teacher preparation communities challenge the legitimacy of science as the basis for knowledge (Fallon, 2006). Critical theorists, for example, have long been concerned about the “objectivity” of “science.” As Wilson and Tamir note, critics of the teacher education establishment decry the preoccupation of some teacher educators with “social justice” as a set of attitudes and beliefs that should be inculcated in future teachers if they are to teach all children well. Yet this ideology is not supported by research. One study of California schools that closed the black-white achievement gap found no relationship between successful learning outcomes and “teacher attitudes and beliefs” (Walsh Symonds, 2004). Teachers who failed at educating children were as likely to believe that “the achievement gaps can be closed and that all children can learn regardless of race or ethnicity,” as were teachers whose teaching actually increased achievement levels for minority children (p. 16).

As a substitute for empirically-based and scientifically-acceptable knowledge, the set of values loosely coupled into “social justice” may be best understood as the latest manifestation of “pedagogical romanticism” (Sedlak, this volume) to beset the field. And the connection between these values and student learning is unclear. The “social justice mission” of the American Educational Research Association, for instance, does not refer to student achievement. NCATE’s “dispositions” give great emphasis to teacher attitudes and self-efficacy concepts that have no empirically demonstrable bearing on whether students in the classroom are learning anything that can be measured objectively.

The endless argument about the “moral basis of education” undercuts claims of legitimacy and professional status. As Fallon (2006) noted recently, the definition of high quality teaching “requires that pupil learning growth be present as an indicator” (p. 147). Evidence about the impact of teacher content knowledge and teaching skills on pupil achievement puts science at the forefront of claims on professional status (Bransford
et al., 2005; Grossman et al., 2005; Ma, 1999), a foundation more stable than the quicksand of ideological debate.

The academy may revel in discussions about knowledge and truth and morality, but schools and policy leaders have real world problems to solve. Because parents and policy makers are not experts, they—like patients in the medical world—must rely on arguments rooted in science and linked to results (Begun & Lippincott, 1993; Starr, 1982).

ENTRY INTO TEACHING: THE OPEN DOOR

One consequence of professional legitimacy is success in using the government’s regulatory power to establish and enforce entry standards. A second consequence is the ability to set and enforce practice standards within the profession. The usual vehicle is licensing boards dominated by members of the regulated profession. Starr (1982) explains the implications of professional status in his study of medicine: “A profession differs from other occupations in part by its ability to set its own rules and standards” (p. 80). The capacity to exert control is Shaw’s “conspiracy against the laity.” Licensure enables practitioners to capture “monopoly profits,” but it may also function to protect consumers (e.g., patients, pupils, customers, clients) (Starr, 1982; Stigler, 1971; Kugler & Sauer, 2002). This suggests that teacher licensure has benefits as well as costs.

Establishing and maintaining authority through the professional community cannot happen, “unless its members agree, first, on criteria for belonging to the profession and, second, on what its rules and standards ought to be” (Starr, p. 80). The absence of these agreements is a defining characteristic of teaching in the U.S. where both the “orthodoxy” and its challengers oppose entry standards. As Wilson and Tamir comment, “if the orthodoxy cannot or will not explicitly and clearly lay out measurable standards . . . the challengers say ‘we ought not to keep people out’ ” (p. 922).

PROFESSIONAL TRAINING

The initial education of professionals generally takes place in academic institutions. Because colleges and universities have credibility in the broader society, this locus of training confers status on those who complete the process. The academic setting thus “validates education based on science” (Begun & Lippincott, p. 61). Over its tortured history, teacher education moved from the schoolhouse to the normal school, and then came to reside in the university (Sedlak, this volume). Today, the locus of training is moving away from the university through “alternate routes” managed by a variety of providers. Without a respected base of scientific knowledge, university-based programs have little but perceived self-interest as a weapon to defend their monopoly on teacher training.

Fights over curriculum are part of the professionalization process in most fields. For teacher education, Sedlak’s discussion of these struggles portrays the combatants and the issues within the academy: “There is no doubt that serious differences in philosophical and political visions divided the groups, and shaped the substance of their claims and campaigns. But private ambitions and collective interests intensified the hostilities” (Sedlak, this volume). As a result of these arguments, teaching never gained the hold over regulators achieved by medicine, engineering, law, and other professions (Begun et al., 1981). This has resulted in approval by the state of alternative sites and agents for the preparation of teachers.

For teacher preparation to be a form of professional education, all education of
prospective teachers must reside within the orthodoxy. Training is an essential component of the credentialing process by which a profession establishes and sustains itself (Begun & Lippincott, 1993; Starr, 1982). But teacher training within the orthodox “social field” takes place at 1323 institutions of higher education in the U.S. (Spellings, 2005). Aside from the huge variety of programs, pathways, course sequences, and degree requirements, never-ending battles over program content successfully undercut claims that training has a scientific knowledge base.

Currently, however, teacher training also exists outside the teacher education establishment. Bourdieu’s “heterodoxy” includes a growing number of teacher training programs operated by non-profit organizations such as Teach for America, individual school districts (the New York City Teaching Fellows is just one example), and for-profit institutions (the American College of Education in Chicago). Although there is no reliable national estimate for the number of these programs and their graduates, it does seem clear that both programs and new graduates are growing rapidly. The very existence of these disparate training sites is empirical evidence for the absence of professional status for teaching and teacher education.

What stands out even to the advocates of university-based teacher preparation is the powerful role of curricular “fads,” and their influence on accreditation. The history of teaching and teacher education often seems to be the story of various “progressive” ideas and their influence (Ravitch, 2000). Among the examples where teacher training seemed more about fads than science, Sedlak describes the “life adjustment” movement in the 1930s, the drift away from subject matter to “methods,” preparing clinical practitioners in programs almost devoid of clinical training, various forms of “pedagogical romanticism” in the 1960s and 1970s, and continual tinkering with ways to teach content areas like mathematics. Many of the most important demands for rigor and coherence in teacher training have come from outside (Sedlak, this volume; Imig and Imig, this volume).

QUALITY CONTROL: ACCREDITATION AND LICENSURE

Program accreditation is part of the process by which a profession sets and applies its own standards and rules. To be effective and respected inside and outside the field, program accreditation must also be rooted in rational and scientific ideas. The same ideas must be embedded in education, licensure, and other form of professional oversight (Starr, 1982; Begun & Lippincott, 1993). Any disjuncture is a barrier to professionalization. Accreditation standards, therefore, must also be seen by those outside the field as effective mechanisms of quality control.

For teacher preparation, these preconditions do not exist. The disarray, conflicts, and shifting rules make accreditation and licensure liabilities in teaching’s quest for professional status (Sedlak, this volume). In contrast to professions, the claims to professional authority of teacher preparation accreditation and licensure do not rest on agreement within the field on rules and standards. Nor do they have the required links with scientific knowledge or with results that benefit the public (Begun & Lippincott). There now are two accrediting bodies, but hundreds of programs neither have nor seek approval through accreditation. Only about half of the university-based programs are accredited by the NCATE or by TEAC. No serious argument can be sustained that these programs are all high quality. Many states do not require that new teachers complete accredited programs, breaking the link (if it ever existed) between training and licensing that professions have established.
The weak knowledge base behind teaching and teacher preparation also means there is no demonstrable relationship between accreditation and program quality. This undermines the case for accreditation. Nor is there much evidence of empirical relationships between the programs themselves and teaching or learning outcomes. Without scientific knowledge—and in the absence of consensus about values or training practices—the argument that all teachers should be trained in a certain way cannot be sustained by teacher educators. Perhaps as a result, teacher education, program accreditation, and government regulation are loosely coupled at best.

Licensure is the standard vehicle for determining entry into a profession (Stigler, 1971; Kleiner, 2000). Stigler argues, “every industry or occupation that has enough political power to utilize the state will seek to control entry” (p. 5). Many of the largest and longest-running controversies in teacher preparation relate to entry standards that may or may not be the object of licensing rules. The Imigs (this volume) note that “there is little agreement on the way to ensure a highly qualified teacher for every student.” This is at least as true within the field as in the wider world of policy makers and the public. The inability of the field of teacher education to adopt and enforce a set of standards that are understood by professionals and the public to be connected to results left the door open to others who were equally worried about schools and students.

The bewildering array of licensing categories, teacher tests, and exceptions to the rules makes it clear that licensing does not contribute to professionalization in teaching. Unlike recognized professions, every state has its own set of laws and rules—and its own way of circumventing them to admit people to practice that are otherwise not qualified. The National Research Council has documented over 600 different teacher tests, with varying content, cut scores for passing, and psychometric properties (NRC, 2001). If the regulatory gate to the classroom is not wide open, it stands ajar in most states.

When the “intense interest” of policy makers and others in teacher education culminated in efforts to develop meaningful national accountability standards during reauthorization of the Higher Education Amendments (HEA) in the late 1990s, many in the field regarded this as meddling (Imig & Imig, this volume). This response drove even a liberal friend of education to comment that “institutions with . . . egregious pass rates [on state teacher tests] are committing a form of fraud on entering students who aspire to be teachers” (Imig & Imig, this volume, p. 895, quoting Senator Jeff Bingaman, D-NM). As Imig and Imig note, the higher education establishment fought diligently against any form of federal accountability for teacher preparation program quality. The battle against disclosure and sanctions for weak programs was led by the nation’s teacher education organizations. Having failed to develop professional standards themselves, they sought to defeat policy makers who acted from outside.

While they could not prevent Title II of the 1998 HEA from including a “report card” on teacher preparation programs, teacher educators had a useful fallback position. The state licensing agencies—which in medicine, the law, engineering and elsewhere use their regulatory authority to set standards based on a recognized body of knowledge tied to results—used their powers to make sure that Title II had no impact on teacher preparation programs under their purview. Of the 1323 university-based teacher preparation programs in the U.S. in 2004, states classified four of them as low performing and 15 “at risk of becoming” low performing (Spellings, 2005). These 19 programs represent just over 1.4 percent of all programs. One has not heard of the teacher education field protesting this abrogation of state responsibility.

Both economists and sociologists make the point that entry standards enshrined in law or regulation protect practitioners from competition. In contrast to the occupations that attained professional status, teaching has been unable to protect itself from other...
entrants into the field. This suggests that teaching has failed to establish itself as a professional community, that its knowledge base lacks scientific authority or public credibility, that teacher education is too divided to develop the standard content and pedagogy that characterize professions, and that its strategies for establishing legitimacy are weak. Critics “do not see some of the hallmarks of professions: internal accountability, an agreed upon knowledge base, specialized and rigorous training, challenging licensure examinations” (Wilson & Tamir, this volume, p. 927). These facets of professionalism do not exist in teaching or teacher preparation. Accreditors, teacher educators, and regulators have, in fact, worked diligently to ensure they are not developed or sustained.

**CHICKEN OR EGG**

Teacher education likes to portray itself as a victim of outside forces. The full story is more complex. As the review of professionalization literature shows, professional status for an occupation is not a gift from the wider world, bestowed by a grateful public in recognition of invaluable contributions to society. Rather, professional status is sought avidly by those in the field, fought for in practice settings and the political arena, and fiercely protected once attained.

Social forces and political developments have inhibited teaching in achieving these same goals. The fact that teaching is a female-dominated occupation is surely one factor (Begun & Lippincott). Frequent changes in state rules do not help. Panic over “teacher shortages” undercut efforts to develop and enforce entry standards (NCTAF, 2003). States and school districts manipulate policy levers to widen the pool of those allowed to teach (Carey, 2006). Licensure regulations are routinely altered to confer legal status on practitioners, no matter their training (NCTAF, 2003). In 2006, the concept “highly qualified teacher” is stretched to cover every teacher in some states, reducing its meaning to the lowest common denominator (Carey, 2006).

While many factors contribute to the problem of professional status for teaching, teaching and teacher preparation themselves have contributed as well. Just as some nineteenth-century physicians and medical educators believed that medicine was more art than science (Flexner, 1910; Flexner, 1940; Starr, 1982), highly individualistic and idiosyncratic notions of teaching contribute to its weaknesses as a professional community. Its professional associations function as trade unions, enforcing the rigid salary structures and contract-based work rules of the factory. High rates of teacher turnover add to the challenge of building a cohesive community with shared, and high, standards. The sometime rejection of science as the basis for teaching and learning and the lack of a widely accepted body of professional knowledge also undercut cohesion.

**CROSSING THE BRIDGE TO PROFESSIONAL STATUS**

The evidence mounts that teachers are the single most important influence on student achievement (Hanushek & Rivkin, 2001; Cochran-Smith & Zeichner, 2005; Rivkin et al., 2005; Fallon, 2006). Policymakers are moving toward defining teacher effectiveness in terms of pupil learning gains instead of relying on the efficacy of “process outcomes” such as degrees and certificates, preparation pathways, program accreditation, and state licensing standards. This is an implicit recognition that credentialing (training, licensure, accreditation) has failed as a professionalization strategy for teaching and teacher preparation.
Control of the external political environment and consensus on specific sets of values within teaching and teacher preparation are beyond us at this moment in time. The most productive strategy for moving toward professional status is to build a base of scientific knowledge about teaching and learning—and apply it to teacher training.

What does this mean for teaching and teacher preparation early in the twenty-first century? It means building on and utilizing findings flowing from efforts to understand the impact of teaching on pupil learning through high quality research designs and sophisticated methodologies. Examples abound: the New York Pathways Project (www.teacherpolicyresearch.org), the Texas Schools Project (www.tsp.org), the North Carolina Education Research Data Center, and the Ohio Teacher Quality Partnership (www.tqpohio.org). Quantitative analyses demonstrate the impact of teachers on pupils, as well as variations within and across preparation “pathways.” Mixed methods research strategies “go behind” large-scale quantitative studies and tease out why certain schools are closing the achievement gap (Walsh Symonds, 2004), and how teaching performance produces pupil learning (Pianta et al., 2006). Raudenbush (2004) explains the value of these contributions to the knowledge base.

Skeptics argue that data from pupil achievement tests are not good enough yet, that methods used in large-scale studies are not relevant to every classroom or every student’s needs, that politics will twist findings and use them against schools and against preparation programs. This may all be true to some extent, but it is beside the point. We can resolve the dilemma of professional status by recognizing the limitations of where we have been, using the new tools and technologies to build an evidence base for sound decisions about the design and delivery of teacher education.

Commitment to scientific inquiry and to the use of evidence has the power to move us in the direction of professional legitimacy. This does not mean that teaching is a mechanistic function where creativity and innovation have no place. In “Science as a Vocation,” Max Weber told his students that science was crucial for artists and musicians of the Renaissance like Leonardo da Vinci. “Science meant the path to true art, and that meant for them the path to true nature. Art was to be raised to the rank of a science, and this meant at the same time and above all to raise the artist to the rank of doctor” (Weber, 1922, 17).

Weber also wrote: “The primary task of a useful teacher is to teach his students to recognize ‘inconvenient’ facts” (Weber, 24). Since there is no widespread commitment by teacher education to anchor education, accreditation, licensure, and practice in scientifically-based knowledge and the use of evidence, each teacher education program must come to grips with the dilemma of professional status.

What to do? Demand of the state that program requirements and teacher performance expectations be raised in the name of quality. Create a teacher education program that subjects itself publicly to higher standards, whether or not the state agrees to strengthen its policies. These steps amount to the same strategy of professionalization that other fields have pursued over the years—putting scientific knowledge, credentialing, training programs, quality control, and policy under the umbrella of a single set of coherent values, enforcing standards that derive from these values, and keeping the focus on outcomes for which the public has respect. Acting on these challenges is the hallmark of a real profession.

REFERENCES

Inspired by Bourdieu’s analysis of the forces that shaped the French higher education system, Wilson and Tamir set out a heuristic for understanding the national forces and counter-forces at play in what would seem to be a simple, straightforward challenge: how to insure that each K-12 student has a competent teacher. Sedlak provides a sweeping historical account of how these forces interacted and evolved from the 1700s onward. The Imigs pick up the story line and provide a microanalysis of these same forces as they shaped teacher policies in the last 25 years.

The analytic framework Wilson and Tamir propose is that teacher education is a social field—in the sense of a force field in physics or a field in sports. The field is populated with forces, agents, or players, who share the field’s logic and rules; who ascribe importance to the “game”; who share some beliefs; who have vested interests in the game’s success and in winning it (in this case, determining who gets to teach). Using Bourdieu, Wilson and Tamir propose that there are two loosely assembled teams: the orthodoxy and their challengers, the heterodoxy. Without each, there is no field, no game, no evolution, and no sustainable solution to the problem.

What is the problem? How to find and retain over 3 million competent teachers. Why is it such a hard one to solve? First, the school’s very mission is contested. Do schools perpetuate the heritage and norms of the past? Prepare productive citizens for the economy and military? Forge a patriotic national identity out of the diversity of those living in the U.S.? Subvert the norms of the past and build a new nation free of injustices and shortcomings? Maximize each individual’s intellectual and social development and potential? Liberate the mind from false doctrine? Second, the logistics of any solution are numerically staggering since there simply are not enough people who are well above the norms on any available measure of teaching talent to fill the needed positions. Third, not enough of those with the requisite talent are willing to do the work, nor are adequate resources available to draw them into teaching. Fourth, we may not have a knowledge base sufficient to the task of making teachers out of non-teachers, regardless of the school’s particular mission or the level of the prospective teacher’s talent.

Wilson and Tamir vividly describe the key national players and their positions: the shifting strategies, arguments, and maneuvers each attempt to put into play; the constant recruitment of players from one side to the other; the defections and realignment of players and strategies. The snapshot of the social field is illuminating and should help those in the field—whether they are the orthodox establishment educationists or the heterodox challengers—to better understand the national field and, more importantly, to better understand and sharpen their own view of teacher quality.

However, the story Wilson and Tamir tell is a national one. But the action—indeed, the social field itself—may better be understood in the local setting of one or another of the nation’s 15,000 school districts and 1,300 teacher education programs. The edicts and
theories debated at the national level invariably have a different character at the local level. On the ground, constructivism becomes synonymous with hands on activity; cooperative learning is a furniture arrangement; standards-based instruction is the addition of a standardized test to traditional instruction; the slogan “less is more” yields only less; “all kids can learn” means no tracking, but differentiated instruction reintroduces it with a new name; and process writing becomes a prescribed number of drafts. More often than not, the new idea is clearer in what it is not than what it is. As a result, activities undertaken in the name of reform tend to only reinforce past practices, for no local actor is really sure what the new idea is; only what it is not. David Cohen (1990) describes Mrs. Oublier, a teacher nominated as the embodiment of California mathematics reforms, who—under scrutiny—was shown to have implemented nearly the opposite of each reform she espoused. In the busy, cacophonous world of the local, one would expect nothing else.

There is a risk to seeing power struggles within the social field as embodiments of universal forces when they are more likely to be rooted in messy localities where ordinary and basic matters drive behavior. The ending of the Cold War revealed, for example, that there really was no monolithic communist threat, but rather a loosely assembled group of individual national aspirations—often in conflict with each other—striving for individual gains. Teacher education and teacher selection goes on with barely an awareness of the agents so clearly delineated in the Wilson and Tamir analysis or in the Imig and Imig catalog of the dynamics of recent events in Washington, D.C. Decisions are driven by the press to fill a particular position, budgetary concerns about sufficient enrollments, and other local values and obligations.

Sedlak’s exposition of the evolution of teaching from a private arrangement between families and tutors to something approaching a teaching profession shows how the seemingly current argument between the orthodoxy and heterodoxy about who should teach is a re-working of earlier tensions. His account also illuminates a host of local factors that shaped whether teachers were best selected from those who could pass a test showing their mastery of the school’s curriculum or those—more or less after 1863—who completed a course of study in pedagogy. Often these factors, like the local factors mentioned above, had little to do with the policy tool itself—teacher testing vs. teacher credentialing—and more to do with local advantage, greed, racism, privilege, and corruption. While Sedlak makes clear that the license to teach by credentials (completion of a teacher education program) became orthodox, the heterodox alternative of the license by testing remains a viable challenge. And not just because the underlying issues remained unresolved. The technology that enabled the earlier widespread teacher testing regime, as Sedlak notes, rested on the invention of the pencil (specifically the No. 2) and the possibility of massive machine scoring. Similarly, contemporary computer simulation technologies promise to make more authentic, embedded, and credible teacher testing possible.

Of course, the current teacher testing policy alternative to the credential still has the limitations Sedlak cites: weak preparation is sufficient to pass the tests, tests with low or no predictive validity, and corruption or incompetence in test administration and execution. The credential, it should be noted, is not without its own examinations and predictive validity. In fact, it has within it some 100 hours of course-based tests in any teacher’s undergraduate preparation, conducted by some 40 independent professors over a four to five year span, and on many samples of behavior and skill. The current standardized teacher tests have two to three hours of one sample and one point in time, hardly the psychometric equivalent of the assessments in the credential. Emerging interactive computer assessment programs might strengthen both heterodox challenge (ABCTE,
for instance) or the orthodox practices (assessments embedded in teacher preparation programs) so that, as Sedlak makes clear, the historical past is not a sure guide to how these issues play out in the future.

The Imigs offer an insider and orthodox interpretation of the forces and counter-forces at work in the social field of teacher education and policy. In their view, the hard-won prior policy tool of certification, which Sedlak documented, became the policy tool of choice by the both the orthodox and heterodoxy (along with the other policy devices including, accreditation, board certification, professional tests, academic degrees and diplomas, and so forth). For the orthodoxy, these devices are the linchpins of a genuine profession, the means—regrettably more than a knowledge base itself—to bring status and respect, remuneration and recognition to teaching. In the Imigs’ compellingly information-rich account, the heterodoxy has taken on each policy device and cleverly supplanted it with a look-alike counterfeit device that allows the heterodoxy to select the most able as teachers (the heterodoxy’s own view) or to select teachers who are merely “good enough” technocrats (the orthodoxy’s view of the heterodoxy’s plan). Perhaps more remarkable than the orthodoxy’s and heterodoxy’s acceptance of certification as the policy tool of choice, according to the Imigs, was the enthusiastic acceptance of the federal government as the preferred instrument of teacher education policy.

The “federalization of teacher education policy” (Imig & Imig, this volume), however, is symptomatic of perhaps a deeper common ground of agreement between the orthodoxy and heterodoxy—an acknowledgment of the severity and magnitude of the problem of low quality teachers and teaching. Throughout our history, federal responses have rarely been sought willingly, but when they are, they concern disasters: stock market crashes, economic depressions, war-like aggression, epidemics, natural catastrophe. What is it that both the orthodoxy and the heterodoxy see about teachers and those who educate them as a national threat that warrants federal policy? Why would section 211 of Title II of the Higher Education Act require, for example, that only programs of teacher education (not programs in accounting, law, medicine, engineering, physical therapy, or nursing) report the pass rate of their graduates on state licensing examinations?1

Perhaps, it is because teaching is different from the other professions. By comparison, it is massive (over 3,000,000 practitioners compared with law’s 400,000) and less well compensated. Perhaps it is because there are over 1,300 schools of education, nearly half unaccredited, in contrast to 180 law schools and 125 medical schools, all of which are accredited. In teaching, unlike most professions, the client does most of the work (students must learn; a lawyer’s clients can do very little to produce justice). Moreover, teachers do not set or control the profession’s standards. The skills of teaching, in contrast to those of other professions, seem quite accessible to lay persons. Indeed, teaching is seen as a natural act. Finally, professional training in teaching is apparently not very difficult, because unlike the other professions, persons of modest abilities are admitted to teacher education programs and almost all earn top marks.

While teaching, as both the orthodoxy and heterodoxy have noted, has all the modern quality assurance mechanisms of the other professions—licenses, certificates, academic degrees, accreditation, standardized examinations, standards boards, prize-awarding professional associations, and so forth—no mechanism has the result we see in other professions. In teaching, at least in the heterodoxy’s mind, there are more false positives. Further, the heterodoxy believes, while many teachers with degrees from accredited schools of education and teaching certificates are not competent, those without those credentials could easily be successful teachers. Departing from the practice of other professional national boards, the formerly heterodox, now orthodox, National Board for
Professional Teaching Standards (NBPTS) apparently agrees since NBPTS certification requires neither a degree in teacher education nor a state teaching license.

As mentioned previously, what is puzzling is why teaching is held to standards that exceed those of the other professions. Other professions have no better evidence of the effectiveness of their training and licensing regimes. Grades in medical and law school, or scores on medical and law license tests, for example, have no greater relationship to the numbers of patients cured or court cases won than the teacher’s grades and license scores have on the number of students who pass state achievement tests. While there are hard-to-teach children and high academic failure rates in impoverished schools, there are also high rates for some diseases (even intractable and incurable diseases) and persistent legal conundrums that require the highest court’s adjudication and readjudication.

The Imigs lament that the “surprising degree of consensus and uniformity” in the late 1990s for the professionalism agenda (based on the National Commission on Teaching for America’s Future (NCTAF) reports) collapsed under the heterodoxy’s orchestrated calls for accountability and autonomy, competition and choice. They overlook the illuminating and emblematic role of the National Partnership for Excellence and Accountability in Teaching (NPEAT) in the collapse. This partnership, lavishly funded at $23 million by the Office of Educational Research and Improvement in 1997, promised that it would ensure the implementation of the NCTAF reform agenda by grounding it in research and marshalling the orthodoxy’s considerable capacity to implement aligned change. The NPEAT was abandoned—unnoticed and without comment—less than two years after its formation. There were many reasons for the collapse, but central was the coexistence of two competing NPEAT goals: (1) the study of the NCTAF agenda and (2) its implementation. NPEAT was to do research about the NCTAF agenda, but apparently only to confirm it so that it might be implemented. The hypothesis, announced as NCTAF propositions, was that the NBPTS, INTASC, and NCATE standards were what mattered most for improving the nation’s schools and they should be required and aligned with all relevant policies and practices. It remained an open question whether NPEAT’s role was to test this hypothesis, or simply assume it was true and move toward the research necessary for implementation. Alternate and competing policy initiatives—alternate routes to certification, vouchers, Teach for America, charter schools, alternative accreditation, or unregulated private school achievement—were never considered or subjected to comparative inquiry. Thus, no effort was made to interrogate, disconfirm, or falsify the NCTAF values and beliefs, and an essential ingredient in scientific and intellectual advancement was lost.

Apart from confusion about whether NPEAT’s point was confirmation or inquiry, the principal issue that remained unresolved was whether NPEAT was fundamentally about (1) building and designing an enduring national partnership, (2) being that partnership, or (3) conducting rigorous research testing the implicit hypotheses in NCTAF’s propositions. Education policy in the U.S. is generally grounded on the orthodoxy’s consensus and the wishes of its powerful constituent groups. NPEAT, in one view, was about grounding education policy in research findings rather than on well-intentioned political consensus. Thus, NPEAT could have changed the norms and values of the social field, providing the means to investigate contentious political issues, like social promotion or class size. This was the value-added of the NPEAT agenda. The policy community would finally have authoritative evidence for its policies, particularly teaching policies.

What is so striking about the NPEAT debacle is not that the orthodoxy’s funder disbanded it, but that the orthodoxy did not continue the partnership on it own as the promised outcomes were essential to its collective agenda. The Imigs describe “a backlash” set out in a heterodoxy’s manifesto, “based on a set of studies and findings that
found all the planks of the so-called professionalization [NCTAF] proposal to be without merit” (p. 12). What the Imigs do not discuss is the empirical merit of those concerns (although they found Secretary Paige’s 2002 Annual Report was hopelessly flawed and without merit). Was the research base of the manifesto sound or not?

The Holmes Group, charter schools, alternative routes into teaching, the National Board for Professional Teaching Standards, Praxis, TEAC have all been summarily rejected by many in the orthodoxy on the grounds that they were allegedly divisive, elitist, insensitive to diversity, unprofessional, and allied with the many enemies of the teaching profession. So too are the orthodoxy’s ideas dismissed by the heterodoxy. The fact that proposals from the orthodoxy and heterodoxy are so single-mindedly and passionately opposed by each other—often without the benefit of investigation—does not help the matter.

Because all known measures and sources of evidence in education are subject to documented distortions and flaws, it is critical that the social field have independent lines of evidence that are beyond reproach on the various aspects of teachers’ competence—whether they have studied and mastered what matters, whether they are entitled to a license, whether they should be hired and tenured, whether they deserve merit payments, promotions, and awards. A rise of public confidence in teaching and its professional license depends on the verification that the field’s jurisdictional systems of the quality control are sound and capable of producing trustworthy evidence. When evidence instead of dogma is central to the rules of engagement—and when independent lines of evidence converge—confidence that the right people are teaching our children might increase and the tensions in the social field might become more mannerly and honorable.

NOTE

1 The Congressional goal was subverted by teacher education programs submitting misleading pass rates of 100 percent because they used the tests as entrance requirements.

Part 8

How do we know what we know?

Research and teacher education

Editors: Marilyn Cochran-Smith and Kelly E. Demers
Part 8
Framing chapters
There have been debates about how, where, by whom, and for what purposes teachers should be educated ever since teacher education emerged in mid-nineteenth-century America. For just as long, there have also been debates about what kind of an activity teaching is and what knowledge and skills teachers need to have in order to teach well. And almost from the beginning, research has played a prominent role in discussions and debates, particularly in disputes about which disciplines are appropriate to the study of education, what counts as educational scholarship, and how evidence should be used to make the case for or against particular approaches to the professional preparation of teachers.

The history and development of research on, in, about, and for teacher education is nested inside of, but also braided with, larger developments in the history of education research generally and in the development of education as a field of study within the university. As Lagemann (2000) points out, the history of educational research throughout the twentieth century was a troubling one, with the “science” of education, based on empirical rather than logical or ideological grounds, a complex and elusive objective. This section of the handbook, “How We Know What We Know: Research and Teacher Education,” makes it clear that the history of research on teacher education has been at least as complex and troubling and the development of a “science” of teacher education at least as elusive.

This section explores the role of research in and on teacher education with a particular focus on changing emphases and major developments over the last fifty years. Woven through the chapters, artifacts and commentaries are explorations of the most enduring questions related to research and teacher education: What can we know about teaching and teacher education from empirical research? What does it mean to talk about a “science” of education/teacher education? How have changing views of science influenced teaching and teacher education over time? What is the history of research in teacher education? What kinds of research are being done and what kinds of research are missing from the field? What is the place of practitioner research, conceptual/analytic work, and critical studies relative to traditional forms of empirical research? How are issues of research methodology related to knowledge access? Whose voices and perspectives have been dominant in the research on teacher education, whose have been ignored or omitted? What are the most important questions to ask empirically? Which concepts and arrangements of school and society should be made problematic, which should be taken as given’s in the research? What are the research designs most appropriate to answer these questions? What purposes and goals should be served by research?

There have been many changes over the last 50 years that have influenced the
nature and development of education policy, practice and research generally. Three of these have had a particularly strong impact on teacher education research: shifts in the major research paradigms and methods used to study educational issues; changes in our understandings of teacher learning and teacher development; and changing notions of educational accountability.

SHIFTS IN PARADIGMS OF EDUCATIONAL RESEARCH

Not surprisingly, the major paradigm shift from positivism to postmodernism in education research generally (and in many other areas of the humanities, arts, and social sciences) had a major impact on teacher education research. Lagemann (2000) suggests that the key influences were: the development of cognitive science, the application to education of research perspectives from anthropology and other interpretive traditions, new relationships between educational research and practice (such as teacher research and design experiments), and the shift from a linear to a systemic view of how research influenced policy. Research on teacher education was shaped by these and by the expanded array of questions, multiple research designs, and broadened problematics of research on teaching, learning and schooling that characterized education research during this time.

Beginning in the late 1970s, there was a great deal of interest in what Erickson (1986) called “a whole family of approaches to participant observational research” (p. 119), which researchers used to study the ecology of classrooms—the social organization of classroom life, how teachers and students together constructed local meanings, and how teaching and learning were embedded within layers of context and culture. Teaching came to be understood as much more than transmitting information. It also included representing complex knowledge in accessible ways, asking good questions, forming relationships with students and parents, collaborating with other professionals, interpreting multiple data sources, meeting the needs of students with widely varying abilities and backgrounds, and both posing and solving problems of practice. Likewise, learning was understood as not just receiving information. Rather the science of learning showed that learning was a process of developing usable knowledge (not just isolated facts) by building on previous knowledge and experience, understanding and organizing information in a conceptual framework, and monitoring progress toward learning goals. Research on teaching began to focus on pedagogy as a social exchange among participants rather than simply the transmission of information from teacher to pupils.

This same general shift was evident in the research on teacher education. Research on teacher education shifted from teacher behavior to teachers’ knowledge, learning, thinking and ideas. Researchers explored how teachers’ attitudes, beliefs and values changed (or not) over time. Although programs and paradigms of research that were considered seminal—even revolutionary—during one period often seemed narrow and wrong-headed later, it was not the case that developments in educational research followed a linear path with new and “better” ways of conceptualizing and studying the issues replacing those that had come before. Rather, the major paradigms of educational research had a dynamic and fluid relationship, with certain approaches to research evolving and continuing in slightly altered forms rather than simply appearing and disappearing.
CHANGES IN UNDERSTANDINGS OF TEACHER LEARNING

In keeping with the larger paradigm shifts noted above, there were major changes in the ways the educational community came to understand teacher learning, teacher development, and the roles teachers could and did play in educational reform. During the decades from the 1970s onward, what some people referred to as a “new image” of teacher learning, a “new model” of teacher education, and even a “new paradigm” of professional development emerged. For prospective teachers, teacher learning was no longer seen as a one-time process of “teacher training” wherein undergraduates were equipped with methods in the subject areas and sent out to “practice” teaching. Similarly, for experienced teachers, teacher learning was no longer seen as a process of periodic “staff development” wherein experienced teachers were congregated to receive the latest information about the most effective teaching processes and techniques. New images of professional development were informed by research about how teachers thought about their work, and emphasis shifted from what teachers did to what they knew, what their sources of knowledge were, and how those sources influenced their work in classrooms.

The general orientation of the “new” approach to teacher learning and professional education was more constructivist than transmission-oriented—the recognition that both prospective and experienced teachers (like all learners) brought prior knowledge and experience to all new learning situations, which are social and contextually specific. In addition, it came to be generally understood that teacher learning took place over time rather than in isolated moments in time, and that active learning required opportunities to link previous knowledge with new understandings. It also was widely acknowledged that professional development needed to be linked to educational reform and needed to focus as much on the cultures of schools and the cultures of teaching as it did on skills training. It was also generally agreed that professional development that was linked to student learning and curricular reform had to be embedded in the daily life of schools in order to be effective and needed to feature opportunities for teachers to inquire systematically about how teaching practices constructed learning opportunities for students and thus supported or constrained access to knowledge.

Very broadly speaking, this new vision of teacher learning was shared by many of those responsible for designing, implementing, and researching programs, projects, and other initiatives that intended to promote teacher learning (Hawley & Valli, 1999). However, “the new professional education” was less monolithic and consensual than was claimed. Beneath the surface, as this section of the handbook reflects, new visions of professional education were different from one another, depending upon differing underlying assumptions about knowledge and practice and differing ideas about the purposes and goals of education (Cochran-Smith & Lytle, 1999).

SHIFTS IN NOTIONS OF EDUCATIONAL ACCOUNTABILITY

The third larger development that influenced research on teacher education was a major change in the way that educators, policy makers and the public understood educational accountability. Along these lines, Cuban (2004) points out that, contrary to the current popular belief that accountability is a relatively new development in education, public schools have, in actuality, never been “un-accountable.” Rather, as Cuban argues, definitions of accountability and quality schooling changed. Prior to and immediately following World War II, what was most important to school boards, administrators and the public was the efficient use of resources to accommodate all those going to school. School
leaders were accountable for providing equipment, supplies and facilities. Schools that did so were considered good schools. After the war, however, social, economic and political changes produced what Cuban calls a “more dramatic” notion of accountability that hinged on results.

The turning point was passage of the Elementary and Secondary Act (ESEA) of 1965 and the many events, acts and court cases leading up to or concurrent with it, including Brown v. Board of Education, the launching of Sputnik, and the Coleman Report (Cuban, 2004). The idea with ESEA was not only to provide funds for improving education but also to attach those funds to new accountability requirements. The reform reports of the 1980s that linked mediocre pupil performance on national and international tests to mediocre economic performance globally spurred new standards and accountability measures in nearly every state, including revised curricula, increased graduation requirements, and new performance standards. There were somewhat parallel developments in higher education.

The standards and accountability movement influenced the shift in teacher education policy and research from inputs to outcomes that occurred during the late 1990s and into present day. As several of the pieces in this section of the handbook make clear, although the current emphasis in teacher education research is on the outcomes and results of teacher education, this was not the case prior to the mid-1990s, when the emphasis was on process—how prospective teachers learned to teach, how their beliefs and attitudes changed over time, what contexts supported their learning, and what kinds of knowledge they needed. During this time, teacher education assessment focused on what is now retrospectively referred to as “inputs” rather than outcomes—institutional commitment, qualifications of faculty, content and structure of courses and fieldwork experiences, and the alignment of all of these with professional knowledge and standards. The shift in teacher education research and policy from inputs to outcomes was part of a shift in notions of educational accountability writ large.

ORGANIZATION OF THIS SECTION

Like preceding sections in this handbook, this section is comprised of three key framing chapters and three artifacts that reflect the enduring nature of questions and issues related to the roles, methods, and uses of research on teacher education. These are followed by three commentaries from authors who bring different perspectives to the topic.

The three framing chapters focus, respectively, on the genres of research most common to the study of teacher education, the history of research on the problem of teacher education, and the epistemological bases of race-based and other alternative critical and qualitative approaches to teacher education research. These three chapters, which represent different takes on the general topic of research and teacher education, were chosen very intentionally. Each offers an overview and a valuable update on issues in the field. Individually, each is worthwhile. But taken together, these three chapters provide a set of complementary lenses for understanding many of the most complex and perplexing questions that have permeated the discourse about research and teacher education for many years. The first two chapters explore traditional territory in research on teacher education with a number of overlapping and complementary points. However the first chapter—on genres—concentrates on research methods, pointing to the persistent use of particular research designs for particular purposes, and linking research on teacher education to larger methodological developments in educational research. This chapter makes it clear that method and purpose are inextricably linked and explores possibilities for linking
across genres. The second chapter—on the history of teacher education research—works from a different angle, concentrating on changes in the prevailing constructions of teacher education as a research and policy problem over time and linking these to contemporary political and policy contexts. The second chapter complexifies judgments about the quality or relevance of the research conducted during one historical period from the hindsight perspective of another. The third chapter—on alternative critical and qualitative research perspectives in teacher education—challenges many of our traditional notions about both the questions and the genres of research on teacher education. It also explores research on teacher education from the perspective of the Black intellectual tradition, concentrating on genres of critical and qualitative research that have implications for social and racial justice.

In the first of the three framing chapters, Borko et al. analyze the genres of research that are most common in teacher education research, analyzing the strengths and disadvantages of each, and connecting these to larger methodological developments in educational and psychological research. The authors offer a thoughtful analysis of how their discussion of genres fits in with previous discussions, suggesting that part of what previous reviews had in common was a sense of participation in and documentation of a new field of study. Borko et al.’s chapter examines four genres of research on teacher education, which they refer to as the effects of teacher education, interpretive, practitioner, and design. Part of what is unique about this chapter is that it offers both a much-needed update of the first two genres, which are reasonably well-established in research on teaching and teacher education, and an examination of practitioner research and design research as emerging and important genres in the field. Their discussion helps to legitimize the importance of these genres and acknowledges the array of approaches researchers have taken to the study of teacher education. For each genre, the authors identify central features and offer detailed analysis of a contemporary example from teacher education. This is followed by an even-handed discussion of the contributions and limitations of each genre. The authors’ thoughtful discussion of the potential of emerging mixed methods and multiple methods studies concludes the chapter.

In the second chapter, Cochran-Smith and Fries shift the focus from research genres to the history of research on teacher education during the early decades of the twentieth century and into the turn of the twenty-first. The Cochran-Smith and Fries chapter focuses on the dominant approach to conceptualizing and studying teacher education during each of four historical periods and links these to the policy, political, and accountability contexts of the times. Although the Cochran-Smith and Fries chapter acknowledges that there were alternative research paradigms as well as trenchant critiques of the dominant approaches during each of these historical periods, it focuses on the dominant ways the problem of teacher education was constructed and studied during each. The chapter argues that we can understand the history of research on teacher education by conceptualizing it as a “problem”—both a research problem to be investigated and the problem or challenge of providing the quantity and quality of teachers needed by the nation—that changed with changing times: teacher education as a curriculum problem, a training problem, a learning problem, and a policy problem. Using the major research syntheses of each time period as historical artifacts, the chapter shows that each conceptualization of the problem of teacher education was constructed in part as a response to the perceived limitations of the previous conceptualization and in part as a response to national concerns about the schools, teaching and teachers. The chapter provides two historical examples for each period as well as a chart that provides valuable detailed information about the key research syntheses from each.

The final framing piece is Joyce King’s chapter on alternative critical and qualitative
approaches to research on teacher education. In previous reviews of teacher education research, critical approaches of the sort King discusses here, have either been omitted or included as the last genre or the final paradigm of research reviewed, often with fewer concrete examples or less full discussions than the others. We have chosen to make this work a separate chapter in this section of the handbook in order to draw full attention to this perspective and thus to counter some of the ways it has previously been marginalized in the field. King argues that the traditional formats and paradigms of teacher education research—which includes most of the research discussed in the first two chapters of this section—have consistently failed to address the mis-education of teachers and students in the nation’s schools where racism and social injustice are perpetuated. Drawing on the interdisciplinary tools of Black studies, King offers an analysis of how critical and qualitative research related to teacher education supports democratic social change and challenges the ideology of white supremacy racism. King describes four interrelated genres of critical and qualitative research on teacher education to show how conceptions of race, identity and culture are implicated in teacher education research—critical race theorizing in teacher education, whiteness studies and teacher learning, critical ethnography, and practitioner inquiry, including action research. King’s provocative chapter suggests that collectively this work can build a “blues epistemology” for teacher education, intended to promote the cultural well-being of diverse populations and counter the dominant ideology. This chapter also includes a very useful chart comparing critical social theory, critical feminist theory pedagogy and methodology; and, critical race theory pedagogy and methodology.

Following the framing chapters, we have included three artifacts that explore some of the central enduring questions concerning how we know what we know about teacher education. The first artifact, “Applying What We Know: The Field of Teacher Education,” is a chapter from The Scientific Basis of the Art of Teaching (1978), Nate Gage’s seminal discussion of the logic and methods of process-product research on teaching. In this chapter, Gage argued that the traditional low status of teacher education was due not so much to its mode of governance or its relative emphasis on liberal arts or pedagogy, but its failure to develop a scientific basis for teaching. In discussing the application of research on teaching to teacher education, Gage explicitly stated that the independent variables of research on teaching (specific teaching behaviors, including teacher-pupil interactions) needed to be regarded as the dependent variables of research on teacher education. We include this artifact in this section of the handbook because it concentrates on one of the most enduring issues related to research and teacher education—the possibility of creating a “science” of teaching and teacher education wherein strategies and methods are based on empirical rather than logical, ideological or traditional grounds. Although now 30 years old, this piece also foresaw many of the issues being debated as part of the current preoccupation with “scientifically-based research” and “evidence-based practice” in education, calling for more connection between research on teacher education strategies and teaching strategies empirically linked to pupil achievement.

The second artifact is Susan Florio-Ruane’s article, “More Light: An Argument for Complexity in Studies of Teaching and Teacher Education.” Florio-Ruane’s article was juxtaposed with Suzanne Wilson, Robert Floden and Joan Ferrini-Mundy’s review of knowledge and gaps in research on teacher preparation (2002) in The Journal of Teacher Education’s special issue on “evidence and inquiry.” This issue of the journal explored from many perspectives the then-emerging press in teacher education to utilize empirical research and evidence as ways to identify and solve policy problems. In her article, Florio-Ruane wrote against this trend, cautioning the community not to narrow the
scope of research on teacher education in the quest to provide answers to very specific—and urgent—questions about “what works” in teacher education across contexts and institutions. Florio-Ruane argued instead for recognizing the broad and complex aspects of teaching, learning, and learning to teach and for engaging in inquiry on many aspects of teaching. Drawing on provocative examples from anthropology, medical research, and literacy, Florio-Ruane pointed out that in other fields, bearing down on particular practical problems with all of the resources of a discipline did not necessarily yield the insights and solutions imagined. On the other hand, she also suggested that close studies of complex processes in particular contexts sometimes yielded new conceptual understandings that were important and relevant far beyond the immediate context. We include this article here because of the enduring issues in research on teacher education it raises—What questions should researchers ask? What disciplinary and methodological perspectives are most likely to yield results that will have far-reaching implications? Who decides which questions get the resources needed for research?

The third artifact is Magdalene Lampert’s article, “Knowing Teaching: The Intersection of Research on Teaching and Qualitative Research,” which appeared in Harvard Educational Review in the year 2000. In the article, Lampert reflected on her own history as an educator and researcher and also on the history of research on teaching as a field to argue that teachers could be active participants in research on teaching, drawing on insider knowledge and experience. She suggested that the inclusion of practitioners in the community of researchers raised particularly knotty questions for qualitative research—the persons or groups responsible for the generation of professional knowledge, the possibilities but also pitfalls of involving the self in social science research, and the ways practitioner research is presented and how its claims are made and supported. Lampert concluded that the inclusion of practitioners in the community of those conducting research on teaching would change both the kinds of data collected and the kinds of analyses and interpretations generated. We chose Lampert’s article for this section of the handbook because, like the other artifacts we have included here, it touches on enduring and complex issues related to research on teacher education. These include questions about voice, presentation and representation in the discourse of research; epistemological issues about what and how we can know about teaching and teacher education and what kinds of evidence it takes to support knowledge claims; and, ongoing debates about who is a legitimate knower and how to account for the tangled relationships of the knower and the known.

This section of the handbook concludes with commentaries from three scholars with different perspectives on the topic of research and teacher education. Robert Floden considers the intertwining of research methods and questions, suggesting that these have a bi-directional relationship. Floden charges that we need to build trust in all kinds of research on teacher education through greater clarity about data collection and analysis methods, more explication of the chains of reasoning leading to conclusions, and explicit distinctions between researchers’ roles as experts and advocates. John Loughran takes on the perennial issues of research and teacher education from the perspective of pedagogy, which, in the European tradition, is not simply synonymous with teaching, but involves relationships, personal engagement, and attention to the conditions and contexts that make educative relationships between teachers and students possible. Loughran suggests that self study is an approach to research on teacher education that draws on insider questions, insights and analyses in ways not possible in research conducted by those outside of teacher education. David Monk offers a practical discussion about what we need to know about teacher effectiveness and preparation that will improve and transform the lives of students. In order to do this Monk suggests that, rather than privileging
one type of research method over another, educational researchers should consider what questions are the most important and then choose the most appropriate research strategy.

REFERENCES

INTRODUCTION

In this chapter we provide teacher educators, educational researchers, and policymakers with an overview to common methods of research in teacher education, emphasizing the affordances, contributions, and limitations of different methods. The development of this relatively new field coincides with a sustained period of vigorous epistemological and methodological debate within the educational research community; in essence, this conversation has involved both calls for and challenges to methodological pluralism. In this larger context, the field of teacher education research has emerged and established itself. While not yet a mature field, and indeed the quality of the research base in teacher education is contested, the rapidly growing body of research reflects the broad range of methods debated in the larger community. Given the challenging questions and problems the field of teacher education seeks to understand, we find this breadth of approaches essential to the field’s vitality and continued development and argue in this chapter for an ongoing commitment to a plurality of approaches.

In preparing this chapter, we first reviewed how other scholars charged with taking a broad look at the field defined its contours. We refer readers to Cochran-Smith and Fries’ chapters in this volume and in Studying Teacher Education (2005), for they provide a useful historical overview to teacher education research. We turn now to highlight other reviews that explicitly address issues and concerns regarding the purposes and methods of teacher education research, and we locate our review in relationship to them.

Reflecting the close connection the field of research on teacher education has had with research on teaching, both the second and third editions of the Handbook of Research on Teaching include chapters addressing research on teacher education (Lanier & Little, 1986; Peck & Tucker, 1973). Peck and Tucker focused their review on experimental studies in teacher education, an approach that reflects the dominance of this method in educational research conducted in the late 1960s and early 1970s; in hindsight, this narrow focus indicates the relative immaturity of the field. Coming thirteen years later at roughly the same time that Division K was established by the American Educational Research Association (AERA), Lanier and Little’s comprehensive review reveals a much more dynamic, multidisciplinary, and contested field. They elaborated enduring problems of teacher education and offered explanations for their persistence. Their review continues to be a landmark for both the elegance of its framework and the impressive number of studies included; as such, it seems to confirm the arrival of research on teacher education as a field. Yet because their purpose was to summarize what research had to say to practitioners, researchers, and policymakers about chronic dilemmas in teacher education, their review is less explicit in its commentary on the nature and quality of the research itself.
In the 1990s three handbooks of research on teacher education were published, marking a new level of maturity of the field (Houston et al., 1990; Murray, 1996; Sikula et al., 1996). Within them, four chapters are devoted specifically to the nature of research (Doyle, 1990; Kennedy, 1996; Lee & Yarger, 1996; Yarger & Smith, 1990). The variation in approaches taken by these authors signals the “intellectual turbulence” (Doyle, 1990, p. 18) of this decade. Yarger and Smith (1990) used their review to call for an organizing framework based on an “antecedent-process-outcome paradigm”; they argued that in order for the field of teacher education research to advance, researchers should pursue an agenda in which studies, from a variety of methodological approaches, examine these three domains and the linkages among them. In contrast, Doyle (1990) seemed encouraged by the growing scholarly interest in teachers’ knowledge and the loosening of “quality control” and “effectiveness” as core themes. He also noted an important methodological shift in teacher education research, as researchers acknowledge the limitations of process-product research designs in helping people understand “. . . how meanings are constructed in classroom settings. To do this kind of analysis, one must have a powerful language to describe both events and the interpretations made of these events” (p. 20, emphasis in original). Six years later, in the second edition of the Handbook of Research on Teacher Education, Lee and Yarger (1996) framed their review by summarizing the recent and swift growth in methodologies employed in teacher education research. They described seven dominant modes of research in teacher education: experimental and quasi-experimental, correlational, survey, case study, ethnographic, historical, and philosophical research. In their conclusion they evaluated the relative impact of findings from studies conducted within these different modes and discussed general issues of quality. They questioned the contribution of the rapid rise in qualitative and narrative modes of inquiry in the field and closed with a call for more interdisciplinary research. Kennedy’s (1996) review takes an intellectually playful look at the credibility of five different empirical approaches to examine the effectiveness of teacher education: She labeled these genres contributions to student learning, comparing the haves and the have nots, ask the teacher, experiments in teacher education, and watch the teacher candidate. What stands out in these reviews is the methodological pluralism of the field and a willingness to critique the methodological rigor of existing studies.

Four more reviews published as the twentieth century gave way to the twenty-first convey even greater urgency regarding the nature and quality of research in this field. Attention to quality reflects the recent policy context in which increasingly vigorous challenges to the effectiveness of teacher education threaten to narrow the questions and methods employed by researchers in this field. Zeichner (1999) used his AERA Vice-Presidential Address to Division K to take stock of the old and new scholarship in teacher education. He closed with his optimistic appraisal of the emergence of self-study as a category of research and with an admonishment to the field to be more globally aware in its search for quality research in teacher education. Sleeter (2001) organized her chapter in Review of Research in Education around four epistemological frameworks found in teacher education research—positivism, phenomenology, narrative research, and emancipatory research. She evaluated each framework for its potential to illuminate the problems associated with preparing dominant-culture teacher candidates to work with the increasingly heterogeneous K-12 learners. Her chapter closes with recommendations to improve research in this critical area, including developing multicultural research teams with expertise in several methodologies and epistemologies, and pursuing more longitudinal studies. Finally, in 2002 the Journal of Teacher Education, Volume 53 (No. 3) explored the theme “evidence and inquiry in teacher education.” Anchoring the issue are essays by Wilson et al. (2002) and Florio-Ruane (2002). Wilson and colleagues called on
the field to examine the rigor of its work: “We, as a field, must make changes that will, in the coming years, give us a better grounding for the practices we believe in or perhaps give us reasons to rethink some practices” (Wilson et al., 2002, p. 201). Some suggestions they offered to ensure high-quality research include: aiming for peer-reviewed journals, making research design and methods more explicit and public, evaluating the quality of studies before citing them, developing more sound impact measures, and designing more large-scale quantitative research. Florio-Ruane’s (2002) essay takes as its point of departure the acknowledged complexity of teaching and learning to teach, and she warned that research must also be complex and varied in its methodological approach.

Unless we keep teaching and teacher education complex, we will fall prey to some or all of the following: pitting approaches of research against one another in the name of rigor; privileging natural science-based approaches solely because of their compatibility with the language and assumptions of policy; failing to recognize that all approaches to research have limited purview; and disregarding insights from critical, alternative approaches.

(p. 214)

Overall, though the purposes, goals, and approaches in these reviews of research on teacher education vary, all convey a certain excitement associated with working on the frontier of establishing a field. Themes that emerge across the reviews include the importance of methodological pluralism, the ongoing concern for rigor and credibility of research, and the desire for the research to have a genuinely constructive impact on teacher education practice and policy. We trust that these themes will be evident in this chapter as well, as we address our charge to explore the various genres that have been central in research on teacher education, considering the central features, contributions, and limitations of each.

In this review of research methods, we feature four genres—effects of teacher education, interpretive, practitioner, and design. The first two—effects and interpretive—are established genres that have contributed substantially and over many years to the knowledge base on teacher education, while the latter two—practitioner and design—have been more recent additions and therefore were not addressed explicitly in previous handbooks (Doyle, 1990; Lee & Yarger, 1996). In choosing these four, we recognize that we leave out research that Sleeter (2001) placed within the “emancipatory” epistemology; others have called this research “critical, feminist, and post-structural” (Zeichner, 1999). We do so because King’s chapter in this handbook addresses this genre. Also, while a number of our predecessors have treated survey research as a mode of inquiry (e.g. Lee & Yarger, 1996; Wilson et al., 2001; Zeichner, 1999), we have not included it as a distinctive genre because we see surveys as a research tool. Studies in any of the genres we feature might, in principle, incorporate surveys in their design.

For each research genre we discuss its purpose and intellectual roots and its central features. We follow this general description with an analysis of a specific study or research program that exemplifies the genre’s key features. We used the following criteria to identify an illustrative study within each genre: (1) quality, that is, the study demonstrates established criteria for rigor within the genre; (2) recency, by which we mean a study published in a refereed publication in the last five years; and (3) topical focus, where the study addresses a current or major issue in teacher education. Within each genre there were several, and sometimes many, studies that met these criteria; where alternatives were available, we chose to feature research programs rather than individual
studies. Given that we could not highlight all studies that met our criteria, our intention is that each example serves as a useful guide to the genre it represents. We close each section with an analysis of the genre’s contributions and limitations. In the chapter’s conclusion, we compare and contrast possibilities of the genres and suggest worthwhile avenues for future research in the field.

"EFFECTS OF TEACHER EDUCATION" RESEARCH

Introduction: purpose and intellectual roots of “effects of teacher education”

Research

“Effects of teacher education” research refers to a body of scholarship concerned with understanding the relationships between teacher education experiences and student learning. With roots in the scientific method of the natural sciences (Guba & Lincoln, 1994; Wardekker, 2000), this research genre seeks to identify generalized patterns of relationships between characteristics of teacher candidates, features of teacher education practices and programs, and learning of teacher candidates and K-12 students through experimental, quasi-experimental, and correlational research methods. Its establishment as a major genre of research was assured by E. L. Thorndike’s argument early in the twentieth century that experimental psychological research and statistical analyses should guide educational research. As founding editor of the Journal of Educational Psychology, in his introduction to the journal’s first issue Thorndike (1910) wrote,

A complete science of psychology would tell every fact about every one’s intellect and character and behavior, would tell the cause of every change in human nature, would tell the result which every educational force—every act of every person that changed any other or the agent himself—would have.

(p. 6)

The legacy of this cause-and-effect orientation is evident in the process-product studies that dominated inquiry in teaching and teacher education in the late 1960s and the 1970s. Early research on effects of teaching was based on a model of looking for relationships between processes (e.g., variables describing classroom practices including teacher and student behaviors) and products (typically measures of student performance on achievement tests). Grounded in the logic of the descriptive-correlational-experimental loop (Rosenshine & Furst, 1973), process-product programs of research sought to describe phenomena of teaching practice, isolate variables that were correlated with student achievement scores, create interventions to train teachers to engage in identified teaching behaviors, and conduct experiments to study the effect of these training interventions (Good & Grouws, 1979). For example, several classic process-product studies identified effective teaching behaviors—such as developing explicit objectives, wait time, and guided practice—that were associated with student achievement (e.g. Dunkin & Biddle, 1974; Emmer et al., 1980; Flanders, 1970; Good & Grouws, 1979; Rowe, 1974; for reviews of major programs of research on effects of teaching see Brophy & Good, 1986; Floden, 2001; Rosenshine & Stevens, 1986). As an extension of this line of thinking, these behaviors became outcome measures in teacher education studies of microteaching (Lanier & Little, 1986; Grossman, 2005).
Microteaching, as an early example of this genre within research on teacher education, reflects the genre’s aim to simplify the complex processes of teaching and learning by identifying and isolating specific variables that influence a targeted outcome. Researchers, who wanted teacher candidates to incorporate proven instructional behaviors into their repertoire, utilized microteaching as an intervention. In a laboratory setting, candidates were introduced to target teaching behaviors, often through expert modeling; they were then videotaped as they practiced the targeted behavior and received explicit feedback during review of the videotape. Measures of teacher candidates’ learning in these studies focused on pedagogical skills and knowledge. While teacher candidates were often able to enact these behaviors in the laboratory settings, they were seldom able to demonstrate transfer to actual classrooms (see Grossman, 2005, for a recent review of microteaching studies). Research on the effects of teacher education broadened over time to include studies examining the impact of components of teacher education such as subject matter preparation, foundations and methods courses, and field experiences (for reviews that include studies in this genre, see Wilson et al., 2001; Clift & Brady, 2005; Floden & Meniketti, 2005).

Although studies within this genre have contributed to the field since its inception, recently, calls to identify “what works” in teacher education have spawned renewed interest in the genre. In the larger conversation about educational research, Slavin (2004) argued, “For questions that compare the outcomes of alternative programs or policies, there is no substitute for a well-designed experiment” (p. 27). This stance on educational research has also been adopted as part of the No Child Left Behind (NCLB, 2002) federal legislation. In their analysis of states’ progress toward implementing NCLB, the Education Commission of the States noted that the act requires programs and practices to be based on “scientifically based research, a phrase that appears in the 2002 legislation 111 times” (Neumann, 2002). The quasi-experimental and experimental designs frequently employed in effects of teacher education research appeal because they align with the U.S. federal government’s recent “de facto definition of good research as consisting of experimental studies that yield prescriptions for action” (Hostetler, 2005, p.16). While experimental studies are clearly encouraged, some of the most recent effects studies have used correlational or structural equation modeling methods because these allow for complex analyses of naturally varying phenomena.

Central features of effects of teacher education research

The fundamental purpose underlying effects of teacher education research is to examine relationships between teacher education experiences and student learning. In effects of teaching studies, the students are K-12 learners; in effects of teacher education studies, the students may be either teacher candidates or K-12 learners. Recent policy questions emphasize linkages between teacher education and K-12 students’ learning. Researchers using the effects of teacher education genre draw upon designs and methods found in the natural sciences. Seeking to maintain objectivity, they specify variables and examine the relationships among them. The researcher looks at the event or phenomenon as an outsider, objectively recording and analyzing data (Florio-Ruane, 2002). Information sources may include pre- and post-tests; observation protocols; and surveys that gather demographic data on teacher candidates, programmatic data (e.g. how many courses in mathematics are required for elementary teacher candidates), and candidates’ perceptions of their preservice experiences. Data analyses typically rely on various statistical methods to determine relationships among variables. These methods of data collection and analysis afford opportunities to include large numbers of participants in a research
Among the different approaches to effects of teacher education research, experimental studies seek to identify causal relationships between conditions and events through the systematic study of planned modifications to the natural world. Researchers manipulate independent variables and then measure the consequences of those manipulations on a set of dependent variables. Ideally, random assignment of participants to experimental groups allows the researcher to attribute changes to a causal relationship between the independent and dependent variables. For example, researchers may randomly assign candidates to two or more clearly defined pedagogical methods in a teacher preparation program, and then assess their knowledge and skills after completion of the program. Correlational research does not attempt to manipulate or control variations in groups; rather, it assesses relationships among naturally occurring variables. Both experimental and correlational research seek to understand relationships among the following: characteristics of teacher candidates, features of teacher education practices and programs, and learning of teacher candidates and K-12 students. The following example is a correlational study utilizing survey data to examine outcomes associated with different routes of teacher certification.

Does teacher certification matter? An example

Goldhaber and Brewer (2000, 2001) conducted a study to examine the relationship between teacher licensure and student outcomes. As they noted, “Although teacher certification is pervasive, there is little rigorous evidence that it is systematically related to student achievement” (p. 141). Furthermore, many states have recently developed alternative routes for teacher certification and for allowing individuals to enter into classroom teaching without having completed a formal teacher education program. These opportunities “make the issue of the relative effectiveness of different types of teacher certification and state certification policies an important one” (p. 141).

In their study, Goldhaber and Brewer compared achievement test performance by students of teachers with standard certification, probationary certification, emergency (temporary) certification, private school certification, and no certification in their subject areas. They also examined whether differences in state licensure requirements are related to student achievement in mathematics and science. The National Educational Longitudinal Study of 1988 (NELS:88), a nationally representative survey of approximately 24,000 eighth-grade students conducted in the spring of 1988, was their primary data source. Additional sources included the NELS parental survey conducted in 1988, surveys of a subset of the students conducted in the spring of 1990 (when the students were tenth graders) and 1992 (when they were twelfth graders), and the NELS:88 twelfth-grade teacher survey. A major advantage of NELS:88 is that it provides teacher and class information that is tied to individual students by subject, thereby enabling researchers to link teacher preparation to teachers to students, and then to estimate value-added models of student outcomes.

In one set of analyses, Goldhaber and Brewer (2000, 2001) used a multiple regression approach to model students’ twelfth-grade standardized test scores in mathematics and science as a function of individual and family background characteristics; and of school, teacher, and classroom characteristics. Consistent with previous research, they found that individual and family background variables explained the majority of variance in students’ test scores. Type of teacher certification is also an important determinant of student outcomes. In their analyses, students of teachers who either were not certified in their...
subject or held private school certification did less well than students whose teachers held standard, probationary, or emergency certification in mathematics. However, students of teachers with standard certification in mathematics did no better than students of teachers with emergency certification. The pattern in science was similar, although the results were not as strong in magnitude or statistical significance.

In another set of analyses they investigated whether the effects of teacher licensing on students’ standardized test scores varied by state. Goldhaber and Brewer tested for possible relationships between states’ licensing requirements (e.g. whether they required any type of teacher exam, whether they required field experiences prior to student teaching) and student achievement. These analyses did not detect any relationships between state licensure policies and student achievement—perhaps, in part, because of limitations in the data set.

Goldhaber and Brewer’s research was constrained by several limitations in the NELS:88 data set. The certification categories used in NELS:88 do not correspond perfectly to definitions of “traditional” and “alternative” licensure used by policymakers and academics. The data set does not contain information on the year or state in which teachers obtained their original certification, thus making it impossible to link state policies to particular teachers. These limitations, coupled with the small sample size of teachers in any particular state, suggest the need for caution in interpreting findings regarding the relationship between state certification requirements and student outcomes. Conclusions regarding emergency certification are also problematic because the subsample of teachers who held temporary and emergency credentials was small, the educational backgrounds of these teachers (e.g. subject matter and pedagogical preparation, previous teaching experience) varied, and requirements for emergency certification differ from state to state (Darling-Hammond et al., 2001). Thus, as Goldhaber and Brewer (2001) acknowledged, “there is not yet enough information to draw strong conclusions about the impacts of certification on the teacher applicant pool” (p. 79) or on student outcomes. Their study informs our understanding of the predictive validity of certification requirements in a context where the presence or absence of certification is fixed (Floden, 2006).

Despite these limitations, the study is noteworthy because it addresses a significant policy question—does teacher certification matter? Goldhaber and Brewer located their study in the ongoing debate regarding the value added by teacher licensure; at the time of the study, the National Commission on Teaching America’s Future had recently issued a major report, What Matters Most: Teaching for America’s Future (1996), which argued for the importance of professional preparation in accredited schools of education. The study’s design illustrates an approach to using a large, publicly available data base to examine relationships between teacher certification and student learning outcomes. The authors provided clear explanations for their regression models and for limitations of these models and the database itself. Careful not to overstate the significance of the associations they identified, they couched their findings with speculative commentary. While not settling the matter of whether teacher certification matters, Goldhaber and Brewer’s study points to the potential value of this type of research for guiding the development of educational policy, and to the importance of additional research that outlines linkages between teachers’ experiences in teacher education and K-12 student learning.

Contributions and limitations of “effects of teacher education” research

Potential contributions of effects of teacher education research derive from the fact that research designs within this genre allow for precise, quantitative predictions; assessment
of cause-and-effect or correlational relationships; and results that are relatively independent of the researcher. The high status afforded to research within the natural sciences extends to effects research within the social sciences in general, and within teacher education in particular. Perhaps the most lasting contributions of effects of teacher education research have occurred within the realm of policy. Educational decision makers find research in this genre useful and attractive because of the relevance and validity of its findings as a basis for designing and evaluating teacher education programs (Florio-Ruane, 2002). The compatibility of the language and assumptions of policy with the language and assumptions of effects of teacher education research also helps explain the intimate relationship between the two. As Cochran-Smith (2003a) explained, when teacher education is constructed as a policy problem the evidence desired to address this problem comes from “experimental or correlational studies with sophisticated statistical analyses, which indicate that certain aspects of teacher preparation do or do not have a systematic and positive impact on pupils’ learning or on other outcomes” (p. 112). As a cautionary note, however, Florio-Ruane (2002) reminded us that the quest for generalizability within the effects of teacher education tradition is often thwarted by the contextual, local, and situated nature of teaching and learning.

Further, many educational scholars have questioned the ability of effects research to impact the practice of teacher education. Burkhardt and Schoenfeld (2003) observed, “Such research provides insights, identifies problems, and suggests possibilities. However, it does not itself generate practical solutions, even on a small scale” (p. 5). The knowledge generated through this research may be too abstract and general for direct application to specific local situations, programs, and individuals (Johnson & Onwuegbuzie, 2004).

In sum, the effects genre is a powerful approach for deriving law-like principles governing the teaching and learning process within the field of teacher education. Darling-Hammond et al. (2001) eloquently captured the potential value of effects of teacher education research:

The field would be well served by thoughtful, well designed and adequately nuanced studies of how different kinds of knowledge matter for teaching, how these can be acquired in various types of teacher preparation programs, and how their acquisition can be represented by state certification policies that provide both useful leverage on training and good information for schools.

(p. 72)

At the same time, there are limitations to the insights this genre can provide; for example, studies cannot always account for why something works or fails to work in particular contexts.

INTERPRETIVE RESEARCH

Introduction: purpose and intellectual roots of interpretive research

Of the four genres addressed in this chapter, interpretive research is perhaps the most expansive category; for example, ethnography, symbolic interactionism, narrative, educational connoisseurship, phenomenology, and discourse analysis all fall within the genre of interpretive research. Because this section cannot do justice to the variety of
approaches within the interpretive tradition, we sketch a broad overview of basic assumptions interpretive researchers make and the basic logic of this genre’s methods.

Interpretive research is, at its core, a search for local meanings (Bogdan & Biklen, 1992; Erickson, 1986; Hatch, 2002; Lincoln & Guba, 1985; Schwandt, 1994). In contrast to effects of teacher education research, which aims to identify stable propositions that apply to multiple situations, interpretive research seeks to perceive, describe, analyze, and interpret features of a specific situation or context, preserving its complexity and communicating the perspectives of the actual participants. Interpretive research searches for “understanding thoughtful action in context” (Florio-Ruane, 2002, p. 209). It seeks to capture local variation through fine-grained descriptions of settings and actions, and through interpretation of how actors make sense of their sociocultural contexts and activities. Given the emphasis on the local, the implications of an interpretive study may address any or all of the following: (1) improving practice, including program design; (2) informing policy by outlining salient contextual features that shape policy formulation or by illustrating successes and flaws in policy enactment; (3) guiding or complementing the design of studies in other research genres, particularly effects of teacher education studies; and (4) shaping theory development. Responsibility falls to readers to determine what explanatory power a study has within their local context(s).

The intellectual roots of interpretive research lie in nineteenth-century European thought, particularly German intellectuals’ interests in understanding the lived world of society’s disenfranchised and in using this understanding to guide social reform (Erickson, 1986; Hatch, 2002; Schwandt, 1994). German social theorists, notably Max Weber, adopted hermeneutical methods within the social sciences. Meanwhile, in the United States, the social sciences, including educational psychology and sociology of education, followed a different path, developing positivist methods and standards of research more closely aligned with the physical sciences (Lagemann, 2000). European thought most influenced anthropologists (e.g. Malinowski et al.) and urban sociologists at the University of Chicago (e.g. Park and Burgess), whose work, in turn, shaped the research of ethnographers interested in education (e.g. Spindler and Kimball). This legacy of nineteenth-century European social thought, though not influential in the field of education during the first two thirds of the twentieth century, garnered the interest of educational scholars in the last third, particularly those who challenged the dominance of experimental and correlational methods in educational research (Guba, 1990; Guba & Lincoln, 1994). Interpretive research has branched out considerably from the work done in the earlier part of the twentieth century and is now an established genre within the field of education (Delamont et al., 2000; Denzin & Lincoln, 1994). Interpretive studies of teaching and teacher education came to the fore as the shortcomings of process-product research became increasingly apparent (Shulman, 1986). Several classic interpretive studies in research on teaching introduced this genre to research on teacher education (e.g. Cazden, 1988; Heath, 1983; Jackson, 1968; Mehan, 1979; Shultz et al., 1982; Tharp & Gallimore, 1988). Collectively, in the 1980s, interpretive studies gave the field an image of teaching as a complex intellectual endeavor that unfolds in an equally complex sociocultural context. Moreover, as the diversity of the student population increased, attention turned to how teachers made sense of both the sociocultural organization of the classroom and the learning and development of students whose lived worlds and experiences were different from their own. One logical extension of this deepened understanding of teaching practice was inquiry into how beginning teachers learn to teach all youth and how different contexts and teacher educators’ practices shape teacher candidates’ learning. This redefined purpose for inquiry in
teacher education—what Cochran-Smith and Fries (2005) have called the “learning problem”—was well suited for an interpretive approach.

Central features of interpretive research

Since the early 1980s, teacher education has seen a dramatic increase in the number of studies conducted within the interpretive tradition. Reflecting both the intellectual vitality of anthropology, linguistics, psychology, and sociology, and the blurring between social science and humanities research, more sophisticated conceptualizations of subject matter, language, learning, identity, and culture have been the focus of theory development. Researchers within the interpretive tradition have drawn upon this theoretical work to forge conceptual frameworks that guide inquiry into the processes of learning to teach and the nature of different approaches to teacher education. No single theoretical framework has dominated the genre, although most recent interpretive studies reflect a sociocultural or situative perspective on learning to teach.

Consistent and distinguishing features of interpretive research include the privileging of “insiders’” perspectives (Cochran-Smith & Lytle, 1993; Florio-Ruane, 2002) and a focus on understanding sociocultural processes in natural settings where individuals learn to teach. Participants’ voice and discourse are critical to capture, so researchers record interactions in naturalistic settings, conduct interviews, and review written artifacts such as reflective journals and, more recently, web-based communication. They ask individuals directly involved in teacher preparation—candidates, school-based professionals working with candidates, and university-based teacher educators—to explicate their backgrounds and to share how they make sense of their practice. Interactions and activities are documented through field notes, artifacts, audiotapes, and videotapes, thus affording researchers opportunities to identify elements of the educational settings that foster, shape, and/or constrain teacher learning. Typically, the researcher defines his or her role as either an observer or a participant observer; that is, he or she comes to know the phenomena under study by spending extended time in the setting and interacting with participants. Interpretive researchers recognize the importance of context by attending to features of a setting, such as physical details; resources and materials; organizational structures of programs, schools, and classrooms; local policies, decisions, and values; and the expected norms of interaction and breaches in those norms. Data analysis is a recursive process that begins during data collection; themes and patterns are developed both inductively from the data and deductively from the conceptual framework.

Unlike effects of teacher education research, interpretive research aims for particularizability, not generalizability.

The task of the analyst is to uncover the different layers of universality and particularity that are confronted in the specific case at hand—which is broadly universal, what generalizes to other situations, what is unique to the given instance. This can only be done, interpretive researchers maintain, by attending to the details of the concrete case at hand. Thus the primary concern of interpretive research is particularizability, rather than generalizability.

(Erickson, 1986, p. 130)

What comprises the grain size or boundaries of the concrete case depends on the researcher’s theoretical and practical focus. For example, a common way of framing a case is around individual candidates or dyads (e.g. mentor/teacher candidate); however, interpretive researchers have also examined specific instantiations of program
components (e.g. effective field experiences), pedagogical approaches in teacher education (e.g. case methods or autobiographical writing), or programs or pathways (e.g. cohort-based program or alternative licensure program). Readers of interpretive studies judge their quality using criteria such as credibility, applicability, transferability, dependability, and confirmability (Eisenhart & Howe, 1992; Lincoln & Guba, 1985; Toma, 2006).

### Appropriating tools for teaching literacy: an example

We feature a cross-institutional, longitudinal research program collaboratively led by Pam Grossman, Peter Smagorinsky, and Sheila Valencia. The common problem studied by these researchers was the “disjuncture between values and practices in the different settings that comprise teacher education” (Grossman et al., 1999, p. 3). Following elementary and secondary candidates from student teaching into their initial years of teaching, the researchers examined “how beginning teachers adopt concepts and practices in the various settings of professional education and then modify and use them in their first few years of teaching” (Grossman et al., 2000, p. 632).

The research design is an elegant example of interpretive research for the following reasons. First, the studies that composed the program were grounded in a shared theoretical framework, activity theory.

Activity theory is predicated on the assumption that a person’s frameworks for thinking are developed through problem-solving action carried out in specific settings whose social structures have been developed through historical, culturally grounded actions. Activity theory is useful for understanding the process of learning to teach, particularly in illuminating how teachers choose pedagogical tools to inform and conduct their teaching. This framework focuses attention on the predominant value systems and social practices that characterize the settings in which learning to teach occurs.

(Grossman et al., 1999, pp. 4-5)

The decision to examine teacher learning through the lens of activity theory guided the researchers toward the study of activity settings, including how individuals constructed them as well as their sociocultural history; identity formation; and tools, both conceptual and practical, that teachers appropriate. A second distinctive feature of the research program was the substantial data set. Across the sites, a relatively small number of teacher candidates were followed intensively through student teaching and, when possible, into the initial years of teaching. Data collection involved multiple interviews of the candidates/novice teachers, observation cycles in their classrooms, interviews with supporting players (e.g. university supervisors, cooperating teachers, school and district administrators), artifacts from concept map activities, and artifacts from classroom practice (e.g. lesson plans, written teaching materials). Third, the data were rigorously analyzed using a collaboratively developed coding scheme. Finally, publications from this research program presented findings through cases of individual teacher candidates, an accessible format well-suited to trace the particulars of each individual’s development as it unfolded in different settings. Moreover, the multiple case studies enhanced the power of the research program by affording opportunities for cross-case analyses. In comparing cases, researchers identified patterns and trends along with individual variation; more important, they were able to explore contextual factors that helped explain both patterns and variation.
Conclusions from this research program have greater impact than smaller-scale efforts by individual researchers, in part because the studies were collaborative and coordinated, and in part because they were longitudinal. The studies make several contributions to a theoretical understanding of teacher learning; for example, the researchers presented a developmental continuum, “five degrees of appropriation,” that explains how novice teachers appropriate conceptual and pedagogical tools such as constructivism or writing workshop (Grossman et al., 1999). They also elaborated upon the tensions that inhere in teachers’ identity formation during student teaching and beyond (Smagorinsky et al., 2004; Smagorinsky et al., 2007). Teacher educators who read the collection of studies from this program may draw insights into teacher education practice. For instance, Grossman and colleagues (2000) illustrated ways in which novice teachers might make sense of curriculum materials that are provided, or prescribed, by their districts; they suggested that teacher educators introduce commercially prepared curricula and invite teacher candidates to analyze these materials during their preservice experience. Finally, the studies inform both teacher education program design and district-level policies because they point out critical disjunctures in teacher candidates’ experiences as they move through the different settings of university courses, student teaching, and induction. For example, Grossman and Thompson’s (2004) comparative analysis of two district policy environments revealed that in participants’ first year of teaching, district policies with regard to curriculum materials, professional development, and mentoring shaped their concerns about instructional and curricular decisions. Such findings have implications for how teacher educators and local school district personnel might work together to facilitate these transitions.

A limitation of this research program is that the transferability of findings depends on whether readers judge the teacher candidate population and contexts studied to be comparable to their own situations. For example, teachers’ appropriation of literacy practices may differ from their appropriation of mathematics practices, or readers may find that the district contexts and policies described in the study are far removed from those they seek to examine and understand.

Contributions and limitations of interpretive research

The interpretive research genre has provided important windows into the thinking of teacher candidates. Teacher educators have drawn upon interpretive research to answer questions about how teacher candidates make sense of learning to teach, and manage the complexities of teaching and learning. Studies have illustrated the importance of candidates’ beliefs and knowledge (e.g. beliefs about teaching and learning, subject matter knowledge), demonstrating how beliefs and knowledge shape and mediate their teacher education experiences. A significant challenge for teacher education has been how to respond to the “demographic divide” (Banks et al., 2005) and prepare teachers for diverse populations. Interpretive studies have provided important insights into the role that candidates’ beliefs about culture, race, and language play in understanding and responding to diverse students, and they have illustrated promising practices in teacher education that help teacher candidates learn to teach in culturally responsive ways. Interpretive studies have also contributed to a substantial body of work examining what occurs within methods courses and field experiences (Clift & Brady, 2005) and the practices of teacher educators (Grossman, 2005). Finally, interpretive studies have helped researchers identify features of high-quality teacher preparation programs (e.g. Darling-Hammond, 2000; Zeichner, 2005b). Taken together, studies within the interpretive genre have given teacher educators a more nuanced understanding of teacher candidates as
learners, and have presented a complex portrait of the impact of teacher education programs and teacher educators’ practices on candidates’ learning to teach.

A central limitation of research in the interpretive genre is the lack of shared conceptual frameworks and designs, which makes it a challenging task to aggregate findings and to draw comparisons across studies, even when those studies are of similar phenomena. Also, though this is not a limitation of the genre per se, many studies make it to print with inadequate discussions of any or all of the following aspects of sound interpretive study design—context and participants, the researcher’s subjective presence, triangulation or member checks, and disconfirming or negative cases. As a result, readers encounter difficulty determining whether and how the findings of a particular study may apply to the situations they work within. A final limitation of the body of interpretive research that has accrued is that it has focused primarily on the perspectives of teacher candidates, teacher educators, and school-based personnel involved in teacher preparation. Broadening an empirical eye to include other stakeholders in teacher preparation—such as university administrators, legislators and school board members, district administrators, those in state departments of education, excellent veteran teachers, parents, and K-12 learners—may yield important findings that speak to the current policy demands to link teacher preparation with student learning.

PRACTITIONER RESEARCH

Introduction: purpose and intellectual roots of practitioner research

In Zeichner’s (1999) assessment of scholarship in teacher education, he hailed self-study research in teacher education—“research about teacher education [that] is being conducted by those who actually do the work of teacher education”—as “probably the single most significant development ever in the field of teacher education research” (p. 8). He characterized teacher educators’ disciplined and systematic inquiry into their own practices as a new genre of research and predicted its growth in importance in the years to come. This genre, which we label “practitioner research,” includes action research, participatory research, self-study, and teacher research. Like interpretive research, it aims to understand human activity in situ and from the perspective of participants; however, it differs in two critical ways, namely the role of the researcher and the overarching purpose for the research. With the researcher as a central actor in the experiences studied, practitioner research examines practice from the inside; that is, instead of research on teacher education by an outside party, it is research by teacher educators about their practice. Implicit in this genre is the belief that practitioners are legitimate knowers who have gained important and valuable perspectives about the situations in which they practice.

Cochran-Smith and Lytle (1990) attributed this genre’s underlying conception of teacher as reflective practitioner to Dewey’s (1904, 1938) ideas about the relationship between theory and practice in teaching and teacher preparation. As early as 1904, Dewey emphasized the importance of teachers being students of teaching, and he advocated that they develop theoretical understandings of teaching and learning through reflection on their practice. More typically, scholars trace the intellectual roots of practitioner research conducted by teachers and teacher educators to the social science action research of the 1950s and 1960s (Cochran-Smith & Lytle, 1990). Lewin (1948), who coined the phrase “action research,” described it as a spiral of cycles of planning, execution, fact-finding, and reflection leading to social action and social change. Stenhouse (1975), one of the
most influential spokespersons for action research in education, encouraged teachers to engage in action research as a way of strengthening their judgment and improving their classroom practice.

The term practitioner research highlights both the personal value of studying one’s own practice and the professional and collective implications of teacher educators formally researching their practice as teachers of teachers. As teacher educators, we have the potential to work at “purposefully unpacking [our] practice in response to the perplexities and uncertainties of teaching about teaching” (Loughran, 2005, p. 8). We do this to deepen our understanding of our own practice, improve our practice, and share our experiences with one another. The knowledge generated through practitioner inquiry is intended primarily to understand and improve practice within a local context. This knowledge may also prove useful beyond local contexts, for example by communicating the complexity of teacher education to the larger community of educators and scholars (Lytle & Cochran-Smith, 1992; Zeichner, 1999). Additionally, practitioner research conducted by teacher educators models for prospective teachers the premise that learning to teach is inherently connected to learning to inquire (Dinkelman, 2003).

**Central features of practitioner research**

The defining feature of this genre is the teacher educator’s dual role as practitioner and researcher. In all variants of practitioner research, the researcher’s professional context is the site for inquiry, and problems and issues within professional practice are the focus of investigation. Often these issues arise from discrepancies between what the practitioner intends and what actually occurs. Because the practitioner is a researcher and the professional context is the site for inquiry, the boundaries between research and practice often blur. Cochran-Smith and Lytle (2004) used the phrase “working the dialectic” to characterize the multifaceted relationship between research and practice inherent in practitioner research. Working the dialectic involves

\[ \ldots \text{reciprocal, recursive, and symbiotic relationships of research and practice, analysis and action, inquiry and experience, theorizing and doing, and being researchers and practitioners as well as the dialectic of generating local knowledge of practice while making that knowledge accessible and usable in other contexts and thus helping to transform it into public knowledge.} \]

(p. 635)

This unique relationship elevates “the local and immediate context to a position of prominence in investigations of teacher education” (Dinkelman, 2003, pp. 14–15), thus creating new opportunities for reflection on and improvement of the practice of teacher education.

All versions of practitioner research also share the features of intentionality and systematicity (Cochran-Smith & Lytle, 1993; Cochran-Smith & Donnell, 2006). Intentionality refers to the planned and deliberate nature of practitioner research, which can be contrasted to other versions of reflective practice that are typically more spontaneous in nature. Systematicity refers to organized ways of gathering information, keeping records of experiences and events, and analyzing the information that has been collected and recorded. Data collection in practitioner research incorporates methods of documentation such as observations, interviews, and artifact collection that are characteristic of many forms of qualitative research. Many practitioner researchers keep organized records of their planning and preparation, copies of instructional materials and assignments,
samples of candidates’ performances on formative and summative assessments, and written reflections about their teaching and their candidates’ learning. Some studies also draw upon e-mail, recorded conversations, narratives, and other data sources that document participants’ perspectives at particular moments in time (Cochran-Smith & Donnell, 2006).

Like many researchers in interpretive genres, practitioner researchers frequently employ both inductive and deductive approaches to data analysis. Occasionally, they use forms of analysis and interpretation that may be less familiar; for example, in “oral inquiry” data analysis is primarily oral, and meaning is collectively constructed in the social interactions of communities of practitioners (Cochran-Smith & Lytle, 1993, 2004). The interweaving of systematic analyses of candidates’ learning (or other educational outcomes) with the teacher educator’s intentions, decisions, interpretations, and reflections enables practitioner researchers to construct detailed accounts of teaching and learning that allow them to derive insights and conclusions not available to outside researchers. The power and authenticity of practitioner research requires multiple approaches to inquiry—multiple sources of data and approaches to data analysis—as well as assurances that the researcher articulates and examines his or her biases and how they may affect data collection and analysis.

One way researchers in this genre ensure quality and rigor is by considering their work to be community property and therefore available to others for review and critique (Shulman, 2000). For this to occur, reports of the research must follow basic conventions of reporting—for example, clearly stating research questions, providing sufficient detail regarding the conditions and contexts in which the study was conducted, and spelling out data collection and analysis procedures. LaBoskey (2004) argued, “We advance the field through the construction, testing, sharing, and re-testing of exemplars of teaching practice” (p. 821). She viewed practitioner research as a vital method for making the practices of teacher education available for deliberation, further testing, and judgment. As Shulman (2000) asserted, by engaging in a scholarship of teaching—by striving to make our documentation, assessment, and analysis of teaching more public and accessible—we not only support the improvement of our own teaching, but also increase the likelihood that the work will be useful to our professional peers.

In many versions of practitioner research, collaboration among teacher educators is also a key feature (Cochran-Smith & Donnell, 2006). Collaboration may involve a range of activities such as writing groups, critical friends, or joint data collection and/or analysis. Practitioner research conducted in isolation from other teacher educators limits the possibility that insights will be shared among colleagues or with wider audiences. Thus, collaboration enhances the likelihood that practitioner research will impact institutional as well as individual change, and will bring theoretical contributions into the public arena. The research program we feature offers an example of collaborative practitioner research.

**Linda Valli and Jeremy Price: an example of practitioner research**

Teacher educators engage in practitioner research at two levels. The first, which is the emphasis of this chapter, is research on one’s own practice as a teacher educator; the second involves facilitating prospective teachers’ experiences as researchers of their own practice. The example that we feature in this section illustrates how both levels can be, and sometimes are, intertwined by researchers who have a commitment to the value of practitioner research in both their own professional lives and in the preparation of their students. Linda Valli (2000) and Jeremy Price (2001) conducted parallel studies of their action research courses for preservice teachers at the University of Maryland. In addition,
they collaborated in a study of their respective action research projects, examining how and what the prospective teachers in their courses were learning about teaching, inquiry, and change (Price & Valli, 2005). These two scholars referred to their research as action research, thereby highlighting their change orientation, which embraces both individual and social-political change.

Valli (2000) located her project in a capstone action research course taken by master’s-level preservice teachers who were also employed as full-time instructional assistants in a local school system. As the instructor, she posed the following research question, “How can this course become more directly linked to school improvement while retaining a focus on the personal development of beginning teachers?” (p. 716). Drawing on data collected through participant observation, interviews with key informants, document review of course assignments, audiotaped class sessions, a reflective journal, and student questionnaires, she found that some students focused their action research on the school level while others focused on the classroom level. Despite her emphasis on both personal growth and school improvement, they were unable to fuse these two foci into one project. Valli concluded that the schools, the course design, and the textbook contributed to this either/or dichotomy, and that strategies for integrating conceptions of teacher and school development “are still in their infancy” (p. 729).

Price’s (2001) action research course in an intensive one-year master’s certification program aimed to provide opportunities for preservice teachers to examine their practice from a social justice perspective and to produce their own knowledge of teaching. His action research explored how experiences in four domains of teacher knowledge central to the course—reflection and inquiry, students, pedagogical content knowledge, and social justice and democracy—helped to shape the candidates’ dispositions and practices as beginning teachers. Using data sources similar to Valli’s, Price found that the action research course provided an opportunity for teacher candidates to develop and expand their ideas, skills, and commitments, and to translate them into teaching practices. He concluded that what teacher candidates learn in an action research course can impact “who they become as teachers and how they see the work of teaching” (p. 71).

Price and Valli (2005) collaborated to explore the pedagogical implications of teaching about and for change in preservice action research courses by looking for patterns and themes across their parallel action research projects. In addition to the multiple sources of data for their individual projects, data for this collaborative research included policy documents and notes from their research meetings. They individually analyzed their own prospective teachers’ experiences with action research and developed descriptive case studies of four students, two from each class. Through a cross-case analysis Price and Valli identified five tensions or dilemmas inherent in the process and pedagogy of action research: individual and institutional change, action and understanding, support and challenge, passion and reason, and regulation and emancipation. They suggested that by working with these tensions, teacher educators can help prospective teachers to examine and reframe assumptions about themselves as teachers and change agents.

This multilayered project exemplifies the dual role as practitioner and researcher that is a defining feature of practitioner research. Further, the focus on individual and social change situates it within the tradition of action research. Price and Valli noted, “. . . like novice teachers, we had much to learn about teaching and that teaching is a complex, moral activity that warrants continuous inquiry and improvement” (p. 60). Their collaborative project demonstrates the value of teacher educators’ action research for simultaneously revealing the complexity of teacher learning, providing a model of inquiry for prospective teachers, and contributing to a theory of the teaching and learning of action research in preservice teacher education.
Contributions and limitations of practitioner research

Practitioner research provides immediate benefits to the teacher educator who is studying his or her practice. These benefits include an increased understanding of content and pedagogy, commitment to a variety of teaching methods, confidence in one’s own ability, and willingness to listen to and learn from students and others (Bullough & Gitlin, 1995; Hensen, 1996). These understandings and commitments derive from teacher educators’ courage to confront and reflect upon “the shortcomings in their work and the gaps between their rhetoric and the reality of their practice” (Zeichner, 1999, p. 12). Hamilton and Pinnegar (2000) argued, “From self study we can evaluate individual practices, understand teaching better, change our practice to respond to the needs of our students, and, most importantly, create practice that stands as an embodied testament to our belief” (p. 238).

The benefits of practitioner research can also extend beyond the teacher educator. As the work by Valli and Price illustrates, “This disciplined and systematic inquiry into one’s own teaching practice provides a model for prospective teachers and for teachers of the kind of inquiry that more and more teacher educators are hoping their students employ” (Zeichner, 1999, p. 11). Practitioner research has the potential to foster educational change and innovations and to open doors for collaboration between K-12 school practitioners and schools of education. Benefits can and should impact the preservice teacher, the teacher education program, the institution of higher education, and the wider community of educators, scholars, and policymakers.

Professionals who engage in research on their own practice face a number of substantial challenges. For teacher educators, challenges such as time and negotiating research agendas within a university culture may constrain systematic inquiry into one’s practice (Bullough & Gitlin, 1995; Cochran-Smith & O’Donnell, 2006). In addition, teacher educators engaged in practitioner research are often called upon to address significant critiques of this research genre. Cochran-Smith and her colleagues (Cochran-Smith & Lytle, 2004; Cochran-Smith & Donnell, 2006) organized the critiques into five categories: the knowledge critique, the methods critique, the science critique, the political critique, and the personal/professional development critique. While a discussion of these critiques is beyond the scope of this chapter, it is important to note that they are fundamentally tied to questions about what counts as knowledge, evidence, effectiveness, and even research. Despite these questions and critiques, Zeichner’s (1999) prediction has clearly come to pass. The genre has continued to grow in scope and impact, as evidenced by numerous publications including the two-volume International Handbook of Self-Study of Teaching and Teacher Education Practices (Loughran et al., 2004) and the new journal Studying Teacher Education, edited by Loughran and Russell.

DESIGN RESEARCH

Introduction: purpose and intellectual roots

Design research is perhaps the most recent genre of research to be used in the study of teacher education and learning to teach. In the educational arena, design research began as a reaction to traditional psychological experimentation, conducted under carefully controlled laboratory conditions, which dominated early research on human learning. Committed to addressing questions about what works in practice, design researchers carried their work into real-life settings, giving up the notions of controlling variables and fixed procedures characteristic of psychological experimentation (Collins, 1999).
Instead, design experiments draw upon models from engineering and “design sciences” such as aeronautics and artificial intelligence to explore learning in context through the systematic design and study of instructional strategies and tools (Design-Based Research Collective [DBRC], 2003). Thus, this genre is characterized by an intimate relationship between the improvement of practice and the development of theory (Brown, 1992; Simon, 1996). The research team works to simultaneously improve practice and contribute to theory by creating models of successful innovations and developing explanatory frameworks about both the processes of learning and the tools that are designed to foster learning (Cobb et al., 2003).

Within education, the most extensive design research projects have been conducted in K-12 mathematics classrooms. Influenced by classroom teaching experiments (Gravemeijer, 1994) and constructivist teaching experiments (Cobb & Steffe, 1983) as well as by design research methodology in other disciplines, classroom-based design experiments typically entail creating an educational innovation and systematically studying learning during its enactment. In teacher education the focus of design research shifts to preservice teachers and their experiences within a teacher education innovation. As Simon (2000) explained, the teacher development experiment methodology “provides a framework for researchers to work at the edge of their evolving knowledge” (p. 336) as they design and enact educational opportunities for preservice teachers, and study participants’ learning and development in the context of those opportunities.

Central features of design research

A hallmark of design research is its commitment to iterative cycles of design, enactment, analysis, and redesign. These cycles are theory-driven; researchers begin with an initial set of conjectures about ways to foster a particular form of learning. These conjectures are refined as they are supported or refuted by systematic collection and analysis of data. New conjectures are similarly subjected to testing and refinement, resulting in iterative cycles of intervention and revision. Design research is process focused; researchers trace changes in an individual or group by examining successive patterns in their reasoning and learning, and assessing the impact of features of the instructional intervention on that reasoning and learning.

The success of design research in educational settings depends on the knowledge and efforts of practitioners as well as researchers. Thus, researchers typically collaborate closely with teachers or teacher educators to develop, enact, and revise an educational intervention. The researchers’ ongoing, direct involvement in the setting is essential. They must have a clear view of the anticipated learning trajectories, a firm grasp of potential means of support, and a deep understanding of the educational setting. These understandings enable them both to facilitate logistics of the innovation and to conduct regular debriefing sessions in which past events are analyzed and interpreted and future ones are planned. Often, the educational practitioner participates fully as a member of the research team, sharing in the collective effort to develop the initial design, conduct the experiment, carry out the analyses, and redesign the innovation. (See, for example, Bowers et al., 1999; McClain, 2003.)

Design research is often multileveled. In teacher education, innovations typically involve multiple elements such as the tasks or problems preservice teachers are asked to solve, pedagogical materials that support learning, norms of participation and discourse that are established, and instructional practices that teacher educators use to orchestrate relations among tasks, materials, and participation norms. In addition to these classroom-level elements, innovations may incorporate activities or structures in the teacher
education program. In sum, design research is iterative, theory driven, process-focused, collaborative, interventionist, and often multileveled (Shavelson et al., 2003).

Although growing out of different scholarly traditions, programs of design research and practitioner research often have several key features in common. A commitment to both improving local practice and contributing to the broader knowledge base, always present in design research, is characteristic of many practitioner research projects as well. When the teacher educator is a member of the design research team and outside researchers participate in practitioner research, the collaborative nature of the working relationships is similar. In addition, there are obvious similarities in both design and intent between action research’s spiraling cycles of planning, execution, fact-finding, and evaluation (Lewin, 1948), and the iterative cycles of design, enactment, analysis, and redesign that are central to design research. Design research also bears more than a passing resemblance to lesson study, in which a professional learning community spends months, or even years, teaching and revising a series of classroom lessons (Cobb, 2000).

Data collected during a design experiment typically include a comprehensive record of the design process—for example, audio or video recordings of design meetings and logs to document evolving conjectures. Of equal importance are data on the learning processes and outcomes and the means by which learning is organized and supported. In a preservice teacher education course, documentation of the intervention typically entails the collection and coordination of multiple forms of data such as audio and video records of class sessions, instructional artifacts, assessment tools and student work, and other products of student learning.

Design research features two distinct levels of data analysis, ongoing and retrospective. During the course of a design experiment, ongoing analyses aim to enhance participants’ learning; these analyses lead to modified conjectures and refined interventions. In a teacher development experiment, these analyses consider prospective teachers’ knowledge and reasoning, and the activity system in which they are situated. Retrospective analyses occur after the intervention is completed and aim to place the design experiment in a broader theoretical context. Through a systematic reexamination of the data, these analyses continue the development of explanatory models of learning and the means by which it can be supported (Simon, 2000; Cobb et al., 2003).

The construction of elementary mathematics project: an example

Almost all examples of educational design research that we found were conducted within K-12 classrooms and focused on student learning. We located a small but growing number of design experiments that addressed teacher learning within professional development (e.g. Clark et al., in press; Lehrer & Schuble, 2000; Stein et al., 1998) and preservice teacher education (e.g. Simon, 2000; McClain, 2003). We feature one of the research programs conducted within preservice teacher education, the Construction of Elementary Mathematics (CEM) Project.

The CEM Project was a three-year teacher development experiment that both generated a set of learning activities to support prospective elementary teachers’ mathematical and pedagogical development and also extended theoretical models of quantitative reasoning and mathematical justification (Simon, 2000). Simon, Blume, and colleagues at Pennsylvania State University studied teacher candidates’ development in the context of an experimental teacher preparation program that coordinated a mathematics course, a course on mathematics learning and teaching, and two related practicum experiences. Primary goals of the program were to increase the preservice teachers’ mathematical knowledge and to foster their development of conceptions of mathematics, teaching, and
learning consistent with reform documents such as the *Curriculum and Evaluation Standards for School Mathematics* (National Council of Teachers of Mathematics [NCTM], 1989) and *Professional Standards for Teaching Mathematics* (NCTM, 1991). Simon designed and taught the two courses; thus, this project is an example of design research in which the practitioner is an integral member of the research team (Cobb, 2000).

The design experiment that Simon and colleagues conducted in the mathematics course focused on prospective teachers’ quantitative reasoning and understanding of multiplicative relationships. The research team began by generating a model of preservice teachers’ mathematical and pedagogical development. Following each class session, they met to discuss their perspectives on the candidates’ mathematical development and to decide on the instructional tasks for the next class. Over the course of the semester, they documented substantial changes in the nature of arguments that the prospective teachers used to justify and validate their mathematical ideas. For example, many of their early attempts to justify a mathematical idea involved invoking authorities such as past teachers and texts. Later attempts involved deductive proofs and taking on the role of arbitrators of validity (Simon & Blume, 1996). On the basis of these ongoing analyses, the research team refined their model of teacher development and revised the learning activities they created to foster preservice teachers’ understanding of multiplicative relationships and conceptions of justification.

Issues that emerged in the ongoing analyses became the foci of retrospective analyses. One set of analyses addressed the development of classroom norms related to justification and validation. These analyses generated an explanation of how mathematical and social norms regarding justification and validation were negotiated in the classroom community, and a description of the factors that affected students’ engagement in mathematical justification and the development of classroom norms (McNeal & Simon, 2000; Simon & Blume, 1996).

In keeping with the goals of design research, these ongoing and retrospective analyses yielded contributions to both practice and theory. Practical products include instructional tasks and pedagogical practices for supporting the development of preservice teachers’ quantitative reasoning and conceptions of justification, and classroom mathematical, and social norms (McNeal & Simon, 2000; Simon, 2000; Simon & Blume, 1994a, 1994b, 1996). Theoretical contributions include an elaboration of a model of quantitative reasoning and an extension of existing taxonomies of mathematical justification. The project exemplifies the iterative, collaborative, and interventionist nature of design research. In addition, it illustrates the blurred boundaries between design research and practitioner research. In fact, in the *Handbook of Research Design in Mathematics and Science Education* (Kelly & Lesh, 2000), the CEM Project is discussed as an example of studying teaching “from the inside” by Ball (2000) and “teacher development experiments” by Simon.

**Contributions and limitations of design research**

As the Construction of Elementary Mathematics Project illustrates, the contributions of design research are both theoretical and practical. Teacher development experiments (like classroom-based design experiments) are conducted around specific interventions in specific contexts. However, the explanatory frameworks developed through ongoing and retrospective analyses enable researchers to compare different enactments of the innovation with respect to key features of the context, teaching and learning practices, and outcomes. These analyses produce detailed accounts of the innovation and its
effects across multiple teacher education settings. Such accounts contribute to contextualized theories of teacher learning— theories that address the elements of context that matter for learning and have implications for teacher education policies and practices (Cobb, 2000; DBRC, 2003).

From a practical perspective, an important goal of design research is that the educational innovations developed in one setting lead to productive patterns of learning when enacted in other settings. The intention is not to develop instructional programs to be replicated in the same way in different contexts; rather, design research is grounded in a conception of teacher educators as professionals who continually adjust their plans on the basis of ongoing assessments of individual and collective activity in the classroom. The explanatory frameworks for analyzing an innovation make it possible to enact the innovation in different settings in ways that preserve its essential elements while adapting to specific features of those settings—that is, ways that do not constitute “fatal mutations” (Brown, 1992).

A key strength of design research is that it enables researchers to test theories and investigate educational innovations as they are enacted in real-world settings. This genre is not well suited to examine the broader sociopolitical context of reform, or to understand an individual’s cognition independent of situation and purpose. Design research is labor intensive and costly. An appropriate time frame for studying teacher development is probably several years—comprising both a long intervention and a long period for retrospective data analysis (Cobb, 2000; Shavelson et al., 2003).

CHALLENGES AND OPPORTUNITIES FOR ESTABLISHED, EMERGING, AND BLURRED GENRES

In this final section we consider the contexts of current policy and practice in teacher education and teacher education research and imagine how the complex questions the field faces will draw upon established and emerging genres and might well inspire the blurring of research genres. We close with suggestions for future directions for genres of teacher education research.

Responding to “dangerous times”

In a 2004 editorial for the Journal of Teacher Education, Cochran-Smith suggested that “these are dangerous times for teacher education” (Cochran-Smith, 2004b, p. 3). Our field faces difficult challenges such as recruiting and retaining a diverse teacher cohort and improving our ability to prepare teachers who ensure all children realize their full potential, especially those who have historically been poorly served in public schools (Darling-Hammond & Bransford, 2005; Florio-Ruane, 2002). At the same time, both critics and stakeholders insist that teacher education demonstrate its contribution to student learning. This current emphasis on accountability, often framed in rather limited terms, has given rise to an environment where learning is defined in terms of what is measurable on tests, where teacher quality is conceptualized as courses taken in a content area and as individual teachers’ effectiveness in raising student test scores, where legislation seeks both to deregulate entry points into teaching and to tighten regulation of university-based teacher education programs, and where legislation calls for science to solve problems in education through “scientifically based research” and “evidence-based education.” The convergence of these developments pushes us toward a narrow conception of teaching and teacher education—“a technical view of teaching, a training model
of teacher education, . . . [and] equating of learning with testing” (Cochran-Smith, 2004b, p. 3).

How can research help us to address these challenges in the current milieu? What kinds of research are most needed to inform the decision making of practitioners and policy-makers? In this section we offer recommendations for directions in teacher education research—directions designed to produce knowledge that will be useful for policy and practice. The notion of complexity features prominently in our recommendations. While research over the last fifty years has given us an understanding of and appreciation for the complexity of teaching and learning to teach, researchers in the next decade must do more to tease out that complexity and relate it to broad notions of student learning. Cochran-Smith (2005) characterized the goal of such a research agenda as building a chain of evidence:

To get from teacher education to impact on pupils’ learning requires a chain of evidence with several critical links: empirical evidence demonstrating the link between teacher preparation programs and teacher candidates’ learning, empirical evidence demonstrating the link between teacher candidates’ learning and their practices in actual classrooms, and empirical evidence demonstrating the link between graduates’ practices and what and how much their pupils learn. Individually, each of these links is complex and challenging to estimate. When they are combined, the challenges are multiplied. (p. 303)

Complex questions call for varied methods

To address these challenges—to build this chain of evidence—our research must be multidisciplinary and pluralistic in its methods and must take advantage of new tools for data collection and analysis. The questions implicit in building this chain of evidence are complex. The field will need to draw upon established genres such as effects of teacher education and interpretive research, continue to develop and experiment with practitioner and design research genres, and blur genres in studies using mixed methods. As Zeichner (2005a) wrote in the concluding chapter of the report of the AERA Panel on Research on Teacher Education, “Given the complexity of teacher education and its connections to various aspects of teacher quality and student learning, no single methodological or theoretical approach will be able to provide all that is needed to understand how and why teacher education influences educational outcomes” (p. 743).

As a field, we must also take advantage of methodological advances to design more complex studies and to engage in multifaceted analyses. New technologies for gathering, recording, and storing information make larger data sets available. New statistical techniques and tools enable multilevel analyses of complex data sets. The digital revolution in media gives researchers the ability to gather and store high-quality audio and video records of teaching and learning activities, and computer software provides new tools to code and analyze textual and video data.

The studies highlighted in this chapter illustrate ways in which both established and emerging genres are incorporating these methodological advances into innovative research designs and analysis plans. We find this work very encouraging. At the same time, we see that there is additional potential in conducting research that blurs the boundaries between genres. In previous decades, larger conversations within the educational research community informed developments in genres of teacher education
research. We expect current discussions of multiple methods will similarly contribute to the field of teacher education research.

Research that incorporates multiple methods in a single project goes by many names—for example, multiple methods, mixed methods, multiple or mixed approaches, multiple or mixed models, or integrated methods (Smith, 2006). Sometimes characterized as the “third methodological movement” in social and behavioral research (Tashakkori & Teddoue, 2003), such research is typically driven by practical concerns. Taking a pragmatic approach, researchers choose multiple methods and combine them in unique ways that offer the best opportunity to address thorny problems. In this sense, building on the central metaphor of this chapter, they are blurring genres to create a richer analysis and interpretation of complex events.

There is much debate about the appropriateness of research that incorporates a combination of methods. This debate examines a variety of issues such as the fit between theoretical perspectives and methods, the conceptual coherence of knowledge claims that are derived from different methods, and the practicalities of conducting studies that combine multiple designs and procedures. A discussion of these issues, most of which remain unresolved, is beyond the scope of this chapter. Here, we illustrate the potential value of such research by briefly describing two studies currently under way—the Teacher Pathways and Teacher Quality Partnership projects. Although in early 2006 these projects were just beginning to publish findings in peer-reviewed venues, given the nature of the questions they address and the strength of their mixed-methods research designs, it is already clear they have the potential to make important contributions to building the chain of evidence that will link teacher education to student learning.

The Teacher Pathways Project is a multiyear investigation of different pathways into teaching in New York City schools; it examines how features of those pathways impact a variety of outcomes such as whether people teach, whether they stay in teaching, and what impact they have on student achievement (Boyd et al., 2006). As such, it is impressive in its purpose and scope. The research team, composed of scholars from several disciplines, includes labor-market economists, teacher educators, and policy analysts. The project incorporates a variety of methods and multiple data sources including individual-level administrative data on characteristics of aspiring and practicing teachers, on teachers’ career histories, and on test scores of elementary math and reading students; survey data on teacher candidates’ characteristics and experiences, on first- and second-year teachers’ experiences and descriptions of school learning environments, and on principals’ descriptions of school learning environments; and interview and artifact data on features of teacher preparation programs and K-12 schools.

All of these data sources are linked at the individual teacher level; survey data on program participants and new teachers are linked to administrative data on their teaching careers and to descriptive information on preparation programs; student test scores are linked to the teachers who taught them; and so on.

(Boyd et al., 2006)

Initial results suggest that teacher attrition varies by pathway. For example, Teach for America teachers experience the highest attrition after two or more years of teaching. The relative rate of attrition for Teaching Fellows and temporary-license teachers is roughly equal after three years of teaching, and is greater than the rate for either college-recommended or individual evaluation teachers. With respect to student achievement gains, in many cases a teacher’s pathway makes little difference, though there are some differences when grade level and years of experience are considered. For
example, in their first year of teaching, alternate-route teachers often provide smaller gains in student achievement than college-recommended teachers, but they typically catch up by their second or third year of teaching. In addition to these patterns identified across pathways, ongoing data collection and analysis are examining the substantial variation within pathways of teachers’ ability to increase student achievement (Boyd et al., 2005).

The Teacher Quality Partnership (2006) is a comprehensive, longitudinal study of how the preparation and development of new teachers in Ohio affects students’ academic performance. The research team, which includes scholars with expertise in measurement, literacy, and teacher education, is conducting a series of studies to explore the relationships among variations in teacher preparation, characteristics and instructional practices of (novice and experienced) teachers, and student learning. Four interlocking research initiatives are under way, with formal data collection taking place from 2005 into 2008. The first initiative, or component, involves surveying student teachers, first-year teachers, and teachers with alternative licensure, asking them to evaluate the coherence and quality of their teacher preparation experiences, particularly as they relate to essential teaching responsibilities. Adapting a theoretical framework from Dunkin and Biddle’s (1974) presage-process-outcome model and using data sources that include surveys, observation cycles, interviews, and artifacts, the second component seeks to “unpack the ‘black box’ of experienced teachers’ classrooms” (Teacher Quality Partnership, 2006). The third traces 50 novice teachers over a three-year period. Using the same protocols as the experienced teacher study, it examines mentoring and induction activities and how those activities support novices’ continued learning, especially their learning to engage K-12 students in tasks that result in their achievement. The fourth component uses structural-equation modeling to analyze the interrelationships among all the qualitative and quantitative data.

New York’s Pathways project and Ohio’s Partnership project aim to understand the wide variation in and impact of the teacher education routes in their respective states. The research designs in both projects address the complexity of the problem and will result in extensive, longitudinal data gathered from a representative sample. While the possibility of oversimplifying or misusing findings from large-scale studies cannot be dismissed, such studies have great potential to contribute to our understanding of several links in the “chain of evidence” Cochran-Smith (2005a) called for. Furthermore, we believe the findings will help teacher educators to critique and reflect on their practice and their programs. These studies utilize both effects of teacher education and interpretive research genres; we hope that the studies’ findings will, in turn, inspire teacher educators to engage in practitioner research and design inquiries.

Future contributions for genres of teacher education research

To conclude this chapter, we offer the following recommendations to guide decisions about genres of research in the study of teacher education:

- **Select research genres and methods of inquiry appropriate for the research questions.** The analyses in this chapter illustrate that there are multiple sound research genres available to the teacher education research community, and that each genre is well suited for some questions more than others. The researcher’s first and most essential role is to pose questions of practical and theoretical significance. Researchers then should evaluate which genre or combination of genres best fits the question(s) and the resources available to conduct a well-designed study.
Continue support for multiple genres of research in teacher education. The analysis of research genres in this chapter shows that no single genre can address the varied and complex questions we pose about learning to teach. Many teacher educators have specialized in research methods most attuned for interpretive and practitioner studies; thus, as a field, teacher education has insufficient ability to conduct studies that both speak to policymakers’ concerns and reflect teacher educators’ deep knowledge about learning to teach. To ensure the vitality of the field, the teacher education community must prepare more researchers with expertise in sophisticated quantitative methodologies. Furthermore, we encourage researchers, no matter what genre they claim as their area of expertise, to recognize the affordances and limitations of each genre and to champion the legitimate contributions each makes to illuminate persistent dilemmas in teacher education.

Build capacity to conduct collaborative research. To conduct the multifaceted, large-scale studies of teacher education that are being called for by many policymakers will require collaboration among researchers with different areas of expertise. In addition to the challenges associated with any collaboration, teams conducting mixed-methods research will need to respond to methodological dilemmas noted earlier in our discussion. While we encourage more attention to mixed-methods design, we recognize that this complex approach to research is still relatively new terrain for researchers in teacher education—terrain whose navigation will require listening and negotiating across disciplinary boundaries (Eisenhart & Borko, 1991).

Demonstrate a strong commitment to rigor in both the conduct and the reporting of research. The value of research hinges on the quality of the design and conduct of each study. As scholars, we must demand that methods of data collection and analysis are carried out with attention to the genre’s major assumptions and quality criteria. Furthermore, research methods and findings must be reported in sufficient detail that quality is evident to consumers. The recently released Standards for Reporting on Empirical Social Science Research in AERA Publications (AERA, 2006) provides useful guidance. An emphasis on the quality of research is especially relevant to the emerging genres—practitioner and design research—as the field is still developing criteria for rigor that honors the innovative features of this research.

As we have argued throughout this chapter, the challenges facing teacher education are numerous and complex. It is all too common for teacher educators and policymakers to attempt to address these challenges—to design and implement programs and policies—without turning to research for guidance (Zeichner, 2005a). In order for research to influence the crafting of wise policy, the improvement of practice, and the development of theory, we must ensure that the research base in teacher education draws from multiple disciplines, is pluralistic in its methods, and is rigorously conducted and reported. Similar recommendations recently have been offered by many other scholars (cf. Borko, 2004; Cochran-Smith & Fries, 2005; Shavelson & Towne, 2002; Sleeter, 2001; Wilson et al., 2002; Zeichner, 2005a). Nonetheless, they bear repeating, as they are essential to ensure that research will play a prominent role in addressing the challenges of policy and practice currently facing teacher education.

NOTES

1 The authors wish to thank Marilyn Cochran-Smith, Bob Floden, and Karen Hammerness for their thoughtful commentaries on earlier versions of this chapter: their astute observations
sharpened arguments and strengthened the piece. The authors, however, take full responsibility for any inadequacies or errors that remain.

2 As evidence of this growth, we note the following: (1) Since 1992 four major handbooks on qualitative research in education have been published (LeCompte et al., 1992; Denzin & Lincoln, 1994, 2000, 2005). (2) Numerous textbooks and guides to conducting this research are available (e.g. Hatch, 2002; Miles & Huberman, 1994), and qualitative methods are an established and expected part of doctoral training in education. (3) New journals have been established to discuss qualitative methods and to publish qualitative work (e.g. Journal of Qualitative Studies). (4) Dynamic epistemological and methodological debates have taken place within established journals (e.g. Educational Researcher).

3 The work of this research program, carried out at two institutions, has been published in several journals. The 1999 article by Grossman et al., “Appropriating Tools for Teaching English: A Theoretical Framework on Learning to Teach,” laid out the program’s collaboratively developed theoretical framework. Findings from the different studies that compose the research program include Cook et al. (2002), Grossman et al. (2000), Grossman and Thompson (2004), and Smagorinsky et al. (2002, 2004, 2006).

4 For example, see the following specific studies: Ball (1990), Borko et al. (1992), Eisenhart et al. (1993), Grossman (1990), Hollingsworth (1989), Holt-Reynolds (1999), Peressini et al. (2004), Stoddart et al. (1993), Wilson and Wineburg (1998). And see the following reviews of literature: Borko and Putnam (1996); Munby et al. (2001); Putnam and Borko (1997); Richardson and Placier (2001); Widen et al. (1998).

5 For example, see the following specific studies: Burrant (1999); Escamilla and Nathenson-Mejia (2003); Fry and McKinney (1997); Gomez et al. (2000); Goodwin (1994); Weiner (1993). Also, see the following reviews of this literature: Hollins and Guzman (2005), Slecter (2001), Weiner (2000), and Zeichner and Hoef (1996).

6 Because a thorough discussion of similarities and differences among the forms of practitioner research is beyond the scope of this chapter, we direct readers to Cochran-Smith and Donnell (2006) and Zeichner and Noffke (2001).

53 Research on teacher education

Changing times, changing paradigms

Marilyn Cochran-Smith
Boston College

Kim Fries
University of New Hampshire

For almost a century and a half, teacher education in the United States has been an identifiable activity with various programs, courses of study, and orientations for prospective teachers and offered by normal schools, colleges, universities, community colleges, and through alternative routes and for-profit providers. And for almost as long, there have been efforts to describe, analyze and improve teacher education by studying it empirically. Over time, the objects of empirical study have varied, including, among other things: the teacher education curriculum, effective methods of teacher training, the knowledge base for teaching, how teachers learn to teach, preparing teachers for diverse populations, the impacts of local and state-level teacher education policies and practices, and the recruitment, selection and retention of teachers. It would be an understatement to say that there has been disagreement over the years about how the nation’s teachers ought to be prepared and how teacher education ought to be studied. Indeed, since its beginnings, teacher education has been a contested enterprise, and research has often played a prominent role in disputes by documenting the current status of the profession, suggesting directions for change, and providing ammunition for major debates.

In this chapter, we outline the recursive but nuanced history of empirical research on teacher education in the United States over most of the last century, from roughly 1920 through 2005. Our major argument is that during these dramatically changing times, the dominant paradigms for conceptualizing and studying teacher education also changed dramatically. We suggest that there were four distinct approaches or shifts during this time period in how “the problem” of teacher education was framed and studied. How a problem or question is framed determines to a great extent how it is answered, which influences how human, fiscal and other resources are expended, what kinds of regulations are established, and what we think we know about a profession. Table 53.1 provides an overview of the four time periods, laying out the rough contours of how the problem of teacher education was constructed and the empirical research that was conducted in keeping with changing constructions.

STUDYING TEACHER EDUCATION

Although it was during the 1950s that research on teacher education (as well as research on teaching) began to proliferate in scope and quantity, we take the 1920s as the beginning point for our analysis. This decade marked the burgeoning of a national effort to upgrade the teaching profession with numerous advisory councils and organizations,

Wilson et al. (2001)  
Cochran-Smith & Zeichner (2005) |
national conferences, annual yearbooks, and multiple institutional self-studies. This was also the decade during which several major empirical reports on the status of teacher education programs and curriculum were issued. Our analysis extends through the turn of the twenty-first century and concludes with research on teacher education published in the early years of the 2000s, with 2005 the publication date of our most recent reports.

We identify four dominant approaches to conceptualizing and studying “the problem” of teacher education during four overlapping time periods: studying teacher education as a curriculum problem during the 1920s through the 1950s; studying teacher education as a training problem from the late 1950s through the early 1980s; studying teacher education as a learning problem from the early 1980s and into the early 2000s; and studying teacher education as a policy problem from the mid-1990s and continuing to the present day. We do not use the phrase, “the problem of teacher education,” in a pejorative sense here, but rather to draw attention to teacher education as the problem or challenge every nation faces in providing teachers for its children and also to refer to how teacher education has been formulated over time as a research problem. Although these four constructions of the problem of teacher education capture the dominant approach of each period, we also note that the history of research on teacher education, like the history of education research generally, is not a steady march over time in which one perspective supplants another (Lagemann, 2000), but is instead more like a “conversation” (Shulman, 1986a, 1986b) among alternative viewpoints and approaches that is dynamic and interactive.

In this chapter, we make a distinction between research on teaching, which refers primarily to investigations of aspects of teaching in K-12 schools where the teachers in question are K-12 teachers and the learners are K-12 pupils, and, on the other hand, research on teacher education, which refers to studies of the preparation of K-12 teachers where the teachers in question are university- or program-based teacher educators and the learners are teacher candidates (and/or sometimes their K-12 pupils). Based on this distinction, we regard research on teacher education as a sub-set of research on teaching.

Since the 1920s, hundreds of empirical studies of teacher education have been conducted. To make this chapter manageable, we drew on this massive literature in two ways. First, we used major syntheses of empirical research on teacher education as historical artifacts, assuming that they reflected the ways of defining and studying teacher education that prevailed in particular periods. We located 38 such syntheses of research on teacher education published between 1920 and 2004. Table 53.2 provides an overview of these syntheses, divided by the time periods during which the problem of teacher education was constructed differently, indicating the kind and quantity of empirical studies reviewed and the general conclusions reached. Second, we used the syntheses from each period to identify two illustrative examples of empirical studies from the period. These provide a way to take a more detailed look at how research questions were posed and how research studies were designed and interpreted.

When we refer to the historical contexts of each period, we mean the larger political, professional and policy contexts that influenced the development of teacher education research. These include public concern about the economy, the welfare of the nation in a changing society and the capacity of the schools to meet the needs of future citizens and leaders. Our discussion of the larger context also includes major commissioned reports about the education of elementary and secondary teachers as well as critiques of existing teacher education programs and educational research. We also consider the governmental and non-governmental regulations and resources that constrain and support teacher education practice and research.
Table 53.2 Syntheses of research on teacher education, 1920s–2005

<td>TEACHER EDUCATION AS A CURRICULUM PROBLEM</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Butsch (1931)</td>
<td>44 studies published between 1920 and 1930. A description of studies included or excluded from this review was not provided.</td>
<td>To summarize the studies of the general and specialized preparation of teachers in institutions, the state and local requirements for preparation, and the devices for in-service training.</td>
<td>• While there is some evidence that the general level of training that teachers receive is improving, it varies greatly between different states, school systems of different sizes, and different classes of teachers. • There is little agreement on the courses best suited for the preparation of teachers. • The standards set by the state certification laws are becoming higher, although still low.</td>
</tr>
<tr>
<td>Butsch (1934)</td>
<td>78 studies on the preparation of teachers, published between 1931 and 1933, including the National Survey of the Education of Teachers (Evendon, 1933). Criteria used to select studies for this synthesis were not discussed.</td>
<td>To synthesize empirical work on TE.</td>
<td>• No overall conclusions were drawn; rather annotations of studies were provided.</td>
</tr>
<tr>
<td>Peik &amp; Hurd (1937a)</td>
<td>500 curriculum reports on higher education at the teacher training, college, and university levels. Studies included were those of “status with historical background, analytic opinion, consensus, experimentation, and measurement” (p. 178). Examination studies were not included unless definitely pertaining to the curriculum.</td>
<td>To review published reports on curricula implemented in liberal arts colleges, junior colleges, general academic subject fields, TE, and curriculum in professional schools.</td>
<td>Yielded 66 concepts found consistently across the reports. Generalizations included: • Changing life and knowledge necessitate continuous curriculum change. • Curriculum depends fundamentally upon their purposes, objectives, and functions. • Individual growth and development are controlling curriculum objectives. • More and better curriculum research, experimentation, and evaluation are needed.</td>
</tr>
</tbody>
</table>
• Broad, distributed, comprehensive curriculum are basic to distinctly specialized curriculums.
• Correlation between theory and practice is a vital consideration.
• Organization and departmental division are important features of curriculum operation and function.
• Basic principles should guide the solution of specific curriculum problems.

Peik & Hurd (1937b) 200 studies on the preparation of teachers published between 1934 and 1936.
Studies included were those with “factual data” or had been published elsewhere.
Of the 200 studies reviewed, 50 referred to general TE curriculum or course considerations.
The remaining studies examined the scope of teacher training, practices and policies, innovations, extracurriculum, graduate work, student teaching, faculty personnel, summer session, college teachers, guidance and personnel, and special fields.

To review studies relative to the preparation of teachers.

Peik (1940) 155 studies on the preparation of teachers published between 1937 and 1939.
Included studies that employed “research procedures;” omitted all unpublished graduate theses.

To review studies on the preparation of teachers.

• Much of the discussion on teacher preparation during this time period focused on the findings of the National Survey of the Education of Teachers (Evendon, 1933).
• There is a need for more research relative to curriculum-pattern analysis, evaluation of innovations, and established practices.
• More curriculum building based upon actual studies of student needs, social needs, and higher levels of desired outcomes is needed.

| Peik (1943) | 138 studies published on the preservice preparation of teachers between 1940 and 1942. Included in this review were a number of extensive descriptions of experimental programs. Not included were unpublished graduate theses. | To review studies on the preparation of preservice teachers. | • All evidence pointed to the need for better scholarship in the profession and for a lengthened period of preparation for every type of position. The trend was definitely away from department majors and minors to broad field majors.  
• There was a growing interest in the internship.  
• An upgrade in the selection of teachers relative to “scholarship and personality” is needed.  
• An improved broad, functional, and somewhat professionalized general education is needed specialized by broad fields rather than by subjects.  
• An increase in the amount of well-supervised practice teaching or a year of supervised internship is needed.  
• A wider consideration of the problems faced by teachers and improvement of instruction in teacher-training institutions is needed, allowing for more student participation. |

| Peik (1946) | 73 studies on the preservice preparation of teachers published between 1943 and 1946. Studies included in this review came from historical sources, expert opinion, and analyses of legal documents, student records, curriculum, or courses-of-study. Also included were studies that used data from questionnaires, interviews, rating scales, and tests or examinations. | To review studies on the preservice preparation of teachers. |
The most important factors for better outcomes of teacher preparation programs are: more careful selection of persons with native competence and good personal qualifications, a functional general education related to our times and conditions, emphasis upon laboratory school experience with children, and more training in professional aspects of teaching that may develop into art and skill.

TEACHER EDUCATION AS A TRAINING PROBLEM

Cyphert & Spaights (1964)

182 studies published on TE between 1953 and 1963

Included studies came from the following sources: journals, Dissertation Abstracts, U.S. Office of Education studies, yearbooks of professional organizations, known researchers in the field of teacher education, data retrieval services, and professional organizations associated with teacher education

Studies concerning teacher behavior and teacher effectiveness (rather than TE per se) were excluded.

To survey, summarize, and annotate examples of research efforts in TE in an un-biased and non-critical manner.

- The extant research in TE is neither extensive nor profound.
- TE research traditionally has been classified in the following ways: historical development, scope, functions of teacher education; organization/administration of teacher education, college faculty/staff; curriculum; instruction/field; student personnel in teacher education; teachers and profession of teaching.

Denemark & Macdonald (1967)

Reviewed studies on the preservice and in-service education of teachers published between 1962 and 1966.

Criteria used to select studies for this synthesis were not discussed

To review the research literature on the education of preservice and inservice teachers.

- Large grants for TE have been given for program development and not for theory development or research activity.
- TE still appears to be fragmented and detached from teaching and from programs of liberal or general education.

<tbody>
<tr>
<td>Peck &amp; Tucker (1973)</td>
<td>Reviewed studies published on TE between 1955 and 1971. Studies included only those utilizing experimental research designs on the process of teacher education (i.e., designs that accurately identify, measure, and account for all of the factors put forth, as well as these factors’ complex and interacting effects). Studies came from journals, books, dissertation abstracts, and final reports of contracted research.</td>
<td>To synthesize studies on TE.</td>
<td>• Promising areas of research development include: preservice-inservice relationships, teacher role differentiation, programs for teachers of culturally disadvantaged youth, and programs built around the integrated use of newer media.</td>
</tr>
<tr>
<td>Koehler (1967, 1985)</td>
<td>220 studies on preservice TE from the ERIC database published between 1980 and 1984. These included surveys of existing practices, evaluations of existing or experimental practices, surveys of practitioners or students concerning their competencies/attitudes acquired from preservice teacher education, measurement studies, ethnographies, and research reviews.</td>
<td>To summarize and analyze the existing research on preservice teacher education.</td>
<td>• A quantum leap occurred, somewhere between 1963 and 1965, in the quality of both the design and the reporting of research in this field. • An accelerating trend toward linking TE to the cognitive, affective, or behavior learning of the teachers’ pupils. • Researchers are “in sight” of the theoretical principles, the operational measures, and even the developmental technology for moving onto a performance-based method of appraising teaching. • More work is needed on conceptualizing the relationship between teacher preparation and teaching practice in order to provide goals and objectives which are possible to attain and have the potential to improve teaching.</td>
</tr>
</tbody>
</table>
Lanier & Little (1986) Research published between the mid-1960s and the mid-1980s. Studies of teacher educators, of prospective and experienced teachers, of the TE curriculum, and of the milieu in which TE takes place were included. Studies on instructional models, modeling, corrective feedback, concept acquisition, and micro-teaching as training strategies in TE were systematically excluded.

To explore how and in what ways might the research on TE not only inform researchers, but also policymakers, professors, administrators, and teachers.

• The body of research leading to a better understanding of those who teach teachers is modest at this time.
• The overall number of preservice teachers has become substantially smaller and composed of fewer academically-talented students than before.
• The relationships between the study of teaching and the curriculum for teachers have received major attention from scholars.
• Institutional policies, structures, and resources that might be expected to foster the quality of teaching and TE appear to do the opposite.

Houston (1990) A synthesis of the knowledge base of TE organized in 48 chapters around the following themes: TE as a field of inquiry; governance of TE; contexts and models of TE; participants in TE; curriculum of TE; processes of TE; evaluation and dissemination; TE in the curricular areas; and broadened perspectives of TE.

The purpose of this “first-ever” handbook on TE was to provide those responsible for preservice and inservice TE with critical syntheses and a careful interpretation of research.

• The conceptual and research base for decisions about TE has never been as strong as it its today.
• There has been notable recent progress, but the research basis is still extremely thin.
• Research and practice needs to be based on what we currently know about TE in order to implement an agenda for consistent, continued development of the field.

Borko & Putnam (1996) Studies selected were representative of research approaches relative to the following conceptual framework:
• The role of knowledge in thinking, acting, and learning.
• Learning as an active, constructive process.
• Knowledge and learning as situated in contexts and cultures.

To examine how knowledge and beliefs change over time as novice teachers learn to teach and experienced teachers attempt to make changes in their teaching practices.

• Learning to teach is influenced by a complex array of factors.
• Prospective teachers’ knowledge and beliefs about teaching, learning, and learners are shaped by years of their own school experience and can be highly resistant to change.

| Studies on teacher socialization or career development were not examined. Although the number of empirical studies reviewed was not made explicit, the authors’ bibliography cites more than 190 references from a variety of sources (i.e. conceptual, empirical, syntheses). | • Experienced teachers’ attempts to learn to teach in new ways also are highly influenced by what they already know and believe about teaching, learning, and learners. • Research shows that with focused and sustained instruction, both preservice and inservice teachers can develop richer and more powerful understandings of subject matter content and transform their beliefs about the nature of the subjects that they teach. • Novices have limited knowledge of subject-specific instructional strategies and thinking of their students about particular subject matter content. • Experienced teachers typically have more knowledge of instructional strategies and of their students, but they often do not have appropriate knowledge and beliefs in the areas to support successful teaching for understanding. • Teachers can learn to teach in new ways, but they require considerable and sustained support to do so. | Sikula et al. (1996) Building on the first handbook (Houston, 1990), the second handbook addressed new developments, changing contexts, and emerging new authorities via 48 research syntheses organized around the

To aggregate the most recent analyses of teaching and TE. | • Schooling and teacher preparation in America are not high-priority items. • Educational reform efforts in America are disjointed, uncoordinated, and often contradictory. |

MARILYN COCHRAN-SMITH AND KIM FRIES
break following themes:
TE as a field of study;
recruitment, selection, and initial preparation;
contextual influences on TE; TE curriculum;
continuing professional growth, development, and assessment; diversity and equity issues; and emerging directions in TE

• The prospects for educational improvement in America in the near future are bleak.
• In recent history, Americans have been unwilling to invest adequate dollars for high-quality public education.
Also presented are two declaratives:
• Improvement in schooling and TE in the United States will be successful to the extent that educators establish via research and make known to the public and to budget controlling authorities the clear relationships that exist between investment in education and productive citizenship.
• Until educators become more proactive, demanding, political, and willing to serve as American Reconstructioneers of Culture (ARCs), educational institutions will continue to drift with the tide of mediocrity as resources flow to other more visible and vocal areas.

Wideen, Mayer-Smith, & Moon (1998)
93 empirical studies, primarily published after 1990 on learning to teach.
The source of these studies included journal articles, electronic databases (i.e. RITE, ERIC), mainstream teacher education journals, and papers presented at conferences including the Annual Meeting of the American Educational Research Association (AERA).

To establish what is currently known about how people learn to teach and to critique the quality of reporting of that research.

• Beginning teachers enter preservice TE with firmly held views about teaching.
• Beginning teachers are little influenced by the interventions that occur in preservice teacher education.
• The homogeneous population of beginning teachers is under-prepared to teach the increasingly heterogeneous population of students.

• Calls for the elimination of coursework requirements for teacher certification.
• Recommends that the average verbal ability score be reported on teachers (by school district) and teacher candidates (by school’s of education).
• Calls for the responsibility of teacher selection and qualification to be moved from the state level to the district level (placing hiring decisions in the hands of principals).
• Suggests that school districts and principals rely on more productive methods for helping teachers gain the instructional skills and knowledge needed to be effective.

Wilson, Floden, & Ferrini-Mundy (2001) 57 empirical studies, published between 1985 and 2000, were examined after initially scrutinizing 313 studies. Studies were discarded from the original set of 313 for four reasons: they were not directly related to the questions; they lacked sufficient rigor; they consisted of arguments based on opinion or principles without empirical evidence; or they were based on a single course in a particular TE program.

Darling-Hammond & Youngs (2002) Examined the research base surrounding 4 assertions put forth To assess whether the 4 assertions and policy recommendations put

and/or instructional skills.
• Calls for the elimination of coursework requirements for teacher certification.
• Recommends that the average verbal ability score be reported on teachers (by school district) and teacher candidates (by school’s of education).
• Calls for the responsibility of teacher selection and qualification to be moved from the state level to the district level (placing hiring decisions in the hands of principals).
• Suggests that school districts and principals rely on more productive methods for helping teachers gain the instructional skills and knowledge needed to be effective.

To summarize what rigorous, peer-reviewed research tells us about key issues in teacher preparation. 5 key questions were posed related to subject-matter preparation, pedagogical preparation, clinical training, teacher quality, and alternative certification programs.

• Showed a positive connection between teacher preparation in their subject matter and their performance and impact in the classroom.
• The pedagogical aspects of teacher preparation matter.
• Clinical experiences are a powerful element of teacher preparation.
• Too few studies exist that can draw significant conclusions about the effect of policies on the quality of preservice teacher education.
• Recent data suggests that most states now have an alternative route into teaching.

None of the assertions presented has strong empirical support.

<tr>
<td>Allen (2003)</td>
<td>92 studies were reviewed out of a total of more than 500 that were originally considered. The 92 chosen studies were all examples of research that met the following criteria: directly relevant to the questions under consideration; published in a scientific journal; published within the past two decades; studied TE in the United States; empirical and rigorous Unpublished reports were not included as well as “a good deal of the local research that teachers or teacher educators conduct in relative obscurity” (p. viii).</td>
<td>To determine the most effective strategies for educating and training the nation’s teachers. Eight questions were posed around the topics of subject-matter knowledge, pedagogical coursework, field-based experiences, alternative routes, teacher effectiveness in hard-to-staff and low-performing schools, entrance requirements for TE programs, accreditation, and institutional warranties.</td>
<td>• The report did not cite the scientific literature that addresses them.</td>
</tr>
<tr>
<td>Cochran-Smith &amp; Zeichner (2005)</td>
<td>3 overarching chapters and 9 research syntheses. These nine syntheses provided a review of the empirical research, primarily looking at the impact of TE on teacher learning, performance, and pupil learning relative to the following topics: • Demographics and teacher quality (90 studies published between 1985 and 2002).</td>
<td>To examine what the research says (and does not say) about preservice TE in the United States To provide an even-handed analysis of the empirical research on the impact of TE with regard to questions of high interest to policy makers and practitioners. To recommend a research agenda to the TE community.</td>
<td>Findings relative to each of the 9 topics are highlighted below: • Demographics: teachers are predominantly female, White, and monolingual; most are prepared in baccalaureate programs at public institutions; teacher turnover is the largest single determinant of demand for new teachers.</td>
</tr>
</tbody>
</table>
• The effects of coursework in the arts and sciences and in the foundations of education (40 studies published between 1990 and 2002).
• Methods courses and field experiences (107 studies published between 1995 and 2001).
• Pedagogical approaches in TE (38 studies published between 1985 and 2001).
• Preparing teachers for diverse populations (99 studies published between 1980 and 2000).
• Preparing teachers to work with students with disabilities (17 studies published between 1990 and 2002).
• Accountability processes (24 studies published between 1990 and 2002).
• TE Programs (38 studies published between 1986 and 2002).

More than 450 empirical studies were included in these 9 syntheses following criteria laid out by Shavelson and Towne (2002) as well as Wilson, Floden, and Ferrini-Mundy (2001).

• Teacher Quality: by graduation, TE program completers have higher average SAT/ACT scores than general pool of college students. Those in the top SAT/ACT quartile are less likely to take jobs as teachers, and once teaching, are less likely to stay.
• Arts and sciences: There is very little research on teachers’ subject-specific study except in math. Studies of teachers’ study of math show positive correlation with high school pupils’ mathematics learning.
• Methods and field experiences: Most research is on how new teachers’ are socialized into the profession, or how beliefs and actions do/ do not change after methods courses and field experiences.
• Pedagogy: Five pedagogies have been studied: laboratory experiences, case studies, video/hypermedia, and portfolios. Studies show shifts in perceptions, knowledge and beliefs, changes in ability to reflect or identify issues, changes in attitudes toward pedagogy or feelings of self-efficacy.
• Preparing teachers to work with diverse populations: Most studies are qualitative, conducted in a single course or field experience, drawing on narrative data. Quantitative studies employ surveys or

<tbody>
<tr>
<td>questionnaires focused on candidates’ beliefs or attitudes. Studies show short-term changes in beliefs and attitudes toward diversity.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Preparing teachers to work with students with disabilities: Studies indicate preservice teachers have positive attitudes about acquiring knowledge and skills to be successful with students with disabilities.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Accountability: Research on certification is limited, but the weight of the evidence generally favors certification over noncertification or undercertification, as measured by student achievement. 42 states require teacher testing, but there is little evidence these have predictive validity. Studies on the impact of accreditation are almost nonexistent.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• TE Programs: Regardless of the type of TE program, subject matter specialization influences teacher retention. Studies comparing the effectiveness of traditional and alternative, 4-year versus 5-year programs have inconsistent or conflicting findings.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This report lays out a research agenda including:  
• (a) research situated in relevant theoretical frameworks; (b) clear and consistent definition of terms;
(c) a fuller description of data collection and analysis methods and research contexts; (d) the development of more programs of research; (e) attention to the impact of TE on teachers’ learning and professional practice; (f) research that links TE to pupil’s learning; (g) multidisciplinary and mixed-methods studies; (h) reliable measures of teachers’ knowledge and skills; (i) experimental research comparing programmatic alternative in terms of outcomes.

Research on these topics: (a) preparing teachers to close the achievement gap; (b) contexts and participants in teacher education; (c) TE curriculum, instruction, and organization; (d) organizational and structural alternatives for teacher preparation; (e) predictive validity of TE program admissions criteria; (f) national databases on teacher candidates, teachers, and reserve pools; (g) research on teacher preparation in various subject areas; (h) systematic analyses of alternative preparation programs and routes; (i) in-depth case studies of programs; (j) research that links preparation with practice and pupils’ learning.
We want to make it clear that our discussion of the history of teacher education research represents only the dominant approaches to conceptualizing the study of teacher education and in no way is intended to suggest that these were the only approaches. In fact, during every period, there were also alternative approaches, thoughtful critics of the dominant views, and differing constructions of the problem of teacher education. We, ourselves, for example have critiqued the policy approach to teacher education research (Cochran-Smith & Fries, 2001, 2005a, 2005b). Historically these critiques and alternative approaches were less visible in the published literature and, with little or no funding, were often marginalized in the discourse. Thus, although the four constructions we describe here capture the predominant approach of each period, it is important to note that, like the history of educational research generally, the history of research on teacher education was not a steady march over time in which one perspective supplanted another. Rather, as noted earlier, the development of research on teacher education involved a dynamic relationship among alternative viewpoints and approaches, with some in the foreground and others more in the background or on the margins.

TEACHER EDUCATION AS A CURRICULUM PROBLEM: EARLY 1920s TO LATE 1950s

By 1921, in order to supply enough teachers, all but one state in the U.S. recognized normal school graduation as evidence of qualification to teach; by the World War I era, this was the practice nationwide (Labaree, 2004). As teacher preparation expanded, studies of the teacher preparation curriculum also began to emerge. One way to make sense of the research produced from the early 1920s to the late 1950s is to acknowledge that teacher education was constructed primarily as a curriculum problem during this time.

Political, professional and policy contexts

The industrialization, urbanization, and immigration of the late nineteenth and early twentieth centuries prompted a shift in the elementary and secondary curriculum—from one that emphasized the classics and was geared for the elite few who were college bound to one that included more subjects and was intended to meet the needs of the mass population (Commission on the Reorganization of Secondary Education, 1918). As a result, however, critics suggested that the curriculum was too broad and inconsistent, with no uniformity in subjects, time allotments, or placement of topics across schools (Thayer & Levit, 1966). Between 1893 and 1895, the National Education Association (NEA) organized committees to examine curricular issues, including: (1) the Committee of Fifteen on Elementary Education; (2) the Committee of Ten on Secondary School Studies; and (3) the Commission on College Entrance Requirements. These committees were dominated by subject-matter specialists. The Committee of Fifteen stressed the three Rs and subject matter compartmentalization at the elementary level (Dewey, 1916), rejecting both kindergarten and child-centered curriculum (Schwartz, 1996). The Committee of Ten recommended nine core subjects for the high school curriculum with “tracking” of students and no art, music, physical education, or vocational education. The Committee on College Entrance Requirements influenced the high school curriculum by recommending a specific number of credits in each subject and requiring the classics for college admission.
Constructing teacher education as a curriculum problem

Not surprisingly, debates about elementary and secondary curriculum had major implications for teacher preparation, especially with regard to the appropriate curriculum for high school teachers (Monroe, 1952). Most agreed that high school teachers needed a thorough education in the disciplines, but disagreed about whether normal schools or colleges and universities should provide this training (Bullough, 2001). Those who supported the normal school model argued that college and university graduates had academic but not pedagogical training and did not know how to manage classrooms or work with children effectively (Brooks, 1907). Those who supported teacher education at the college and university level argued that normal schools trivialized education by emphasizing method, gearing the curriculum to the lowest level students, and not providing the deep scholarship and liberal education that universities did (Bolton, 1907).

During the 1910s and 1920s (and continuing for much of the century), Teachers College laid out a “union of progressivism and professionalism” (p. 159) as a blueprint for the curriculum of teacher preparation (Labaree, 2004), which included: “general culture” (general knowledge), “special scholarship” (learning across several disciplines), “professional knowledge” (a systematic inquiry into the theory and practice of education), and “technical skills” (practical pedagogical skills) (Cremin, 1978; Lucas, 1999). Interestingly but not surprisingly, none of these recommendations was based on empirical evidence that time spent in preparation programs or time studying curricular theories actually led to the outcomes that were desired (Herbst, 1989; Lucas, 1999). Between 1920 and 1940, there was a push to upgrade the teaching profession by studying the core traits of effective teachers and adjusting the teacher education curriculum accordingly so there would be a more unified and consistent approach across institutions.

Studying teacher education as a curriculum problem

The push to upgrade the profession prompted several massive investigations into the teacher education curriculum. Using surveys, interviews, and observations of teacher preparation schools, the point was to identify the key characteristics and skills of effective teachers and find out whether these were being taught in the curriculum across institutions. Inspired by the Flexner report on medical education, the Learned-Bagley (1920) report recommended that teachers’ work be evaluated on the basis of pupil growth and that all teacher preparation courses be professionalized and offered at single-purpose college level institutions (Imig & Imig, 2006). The two most important studies of the period were the Commonwealth Teacher-Training Study (Charters & Waples, 1929) and the National Survey of the Education of Teachers (Evendon, 1933), which are detailed below.

Between 1930 and 1945, there were efforts to codify and unify teacher preparation, a movement stimulated by changing curricular and certification requirements (Haskew, 1960). The push to collect more than simple descriptions of programs and curricula was followed by a call for statistical summaries, surveys by experts, and correlational studies applied to curricula (Travers, 1983). The first syntheses of research on teacher education were published in the Review of Educational Research during the late 1930s.

Butsch (1931), for example, summarized “studies of general and special preparation of teachers in institutions, the state and local requirements for preparation, and the devices for in-service training” (p. 76). He found little agreement on the courses and/or curriculum best suited for the preparation of teachers. Several years later, Butsch provided a
second synthesis drawing primarily on the data from the National Survey of the Education of Teachers, Peik’s summary of the National Survey, and several more regionalized studies (Butsch, 1934). He examined the demographic studies on teachers, their levels of training, where they obtained training, and the professional coursework required for state licensure (e.g. educational psychology, general survey courses, student teaching, history of education, special methods, and tests and measurement).

Later in the decade, Peik and Hurd (1937b) reviewed more than 500 reports relative to higher education curricula. Studies of teacher education focused on curriculum building, subject matter divisions, professional courses, and the integration of theory and practice. The authors called for more and better curriculum research, experimentation, and evaluation as well as the establishment of centers for cooperative curriculum research. In later reviews, Peik and Hurd (1937a) and then Peik (1940, 1943, 1946) called for a broader curriculum in both professional and subject matter areas with longer periods of practice, better supervision, more experience with students, more attention to teaching problems, and improved teacher training instruction. These reviews also recommended studies of students’ and social needs, clearer and more rigorous outcomes, and carefully planned experimentation along with valid and reliable evaluations.

**Studying teacher education curriculum: two examples**

We offer two examples of research on teacher education, conceptualized and studied as a curriculum problem. The Commonwealth Teacher-Training Study (Charters & Waples, 1929) was intended to use scientific means to identify key teacher traits in order to improve teacher preparation across the nation. The National Survey of the Education of Teachers (Evendon, 1933) was conducted under the auspices of the U.S. Commissioner of Education based on a mandate from Congress that a nationwide survey of the education of teachers be carried out.

The point of the Commonwealth Study was to find out scientifically what the most important traits of teachers were, isolate and represent these traits on charts, lists, and formulae including minute behavioral components, and then use these to guide teacher preparation. Charters and Waples (1929), researchers from the University of Chicago and the principal investigators of the study, led a large team of researchers who took as a premise that curriculum development should be guided by scientific principles (Zeichner, 2005b). As Zeichner suggests, this investigation was based on the assumption that the teacher education curriculum ought to be “radically reorganized” because it did not operate from “a clear definition of objectives and logical plans of procedure” (p. 7).

Charters and Waples and a large team of researchers used the research method of “consensus” wherein they interviewed teachers, administrators, parents, professors of education, and students in order to find out what these stakeholders believed to be the key characteristics of teachers in different contexts (Zeichner, 2005b). Their nominations were then reviewed by a large panel of judges, and 83 traits of effective teachers were defined, rank-ordered by importance, and matched with multiple indicators. Interestingly, as Imig and Imig (2006) point out, the idea of drawing on research and experience to develop professional consensus about the knowledge and skills teachers need to be effective is a strategy that has been used many times throughout the history of teacher education research, including the development by Goodlad (2002) and other professionals and policymakers of “postulates” to guide the teacher education curriculum and, most recently, the development by Darling-Hammond and Bransford (2005) and a large committee of experts of the major knowledge domains that the curriculum for all beginning teachers should include.
Charters and Waples’ list of teaching traits included adaptability, alertness, inspiration, leadership, tact, witiness, calmness, and magnetism, each of which had multiple indicators—some as many as 12 (Zeichner, 2005b). The process for developing this list was extensive and what many people would term “excessively” quantitative, involving multiple tabulations, categorizations, and sub-categorizations of traits, characteristics, and indicators. Zeichner (2005b) described the research process this way:

Following the identification of the traits of good teachers, Charters and Waples employed job analysis techniques and collected a comprehensive list of the activities of teachers by mailing surveys to teachers in 42 states. The final list of 1,001 activities was subdivided into seven major divisions such as instruction and classroom management. Over 200,000 statements were analyzed to get to the final list. Some of these activities get right to the heart of teaching and can be found in contemporary teacher standards such as the INTASC standards.

Although Charters and Waples concluded that teacher-training institutions should use their lists of traits to guide the curriculum and to help determine course revisions and program offerings (Kliebard, 1973; Lagemann, 2000; Travers, 1983), their report had little impact on the curriculum of teacher education programs. Interestingly, however, and for better or worse, the Charters and Waples’ (1929) report was the beginning of the development of performance-based standards development in teacher education, an approach that is alive and well today.

The second example of research on teacher education as a curriculum problem is the National Survey of the Education of Teachers (Evendon, 1933), which relied primarily on surveys as a research method. In 1929, following the Commonwealth Study, Congress mandated that the U.S. Commissioner of Education undertake a nationwide survey of the education of teachers. This mandate was supported by a number of organizations that were involved in larger efforts to professionalize teaching and teacher education—the American Association of Teachers Colleges (established in 1923), the National Council of State Superintendents and Commissions of Education, the Association of Deans of School of Education and the North Central Association of Colleges and Secondary Schools.

This six-volume report, put together by a team of researchers led by Evendon, was the outcome of the first-ever national survey on teacher education in the United States. The study utilized the prevailing education research design of the time—the survey method—to study the curriculum of teacher education by collecting and organizing data in a scientific manner (Lagemann, 2000). This report provided extensive information about the standards and status of training institutions, the demographics of teachers, and the policies and patterns of recruitment, selection, and licensure. However, its main emphasis was on the teacher education curriculum, particularly what was actually being provided to and required of teacher candidates in the variety of programs throughout the United States.

The National Survey of the Education of Teachers (Evendon, 1933) called for: (a) an increase in the amount of teacher preparation, academic studies, professional studies, and classroom practice; (b) more research on teacher education; and (c) preparation programs that reflected the proven characteristics of effective teaching. As a result, teacher preparation programs increased curricular requirements in general education, separated secondary from elementary methods, and deemphasized general methods in favor of subject-specific methods. In addition, coursework in the history of education lost
out to courses in philosophy, psychology, and measurement (Cottrell et al., 1956; Cremin, 1953).

The value of studying teacher education as a curriculum problem

The period of time when teacher education was defined as a curriculum problem marked the first attempts to study teacher education empirically and to use “scientific” methods to improve preparation. Those who carried out the curriculum studies during the 1920s, 1930s and 1940s were involved in early efforts to establish professional consensus—based on empirical data and professional experience—about what teachers should know and be able to do, a quest that has endured throughout the history of research on teacher education. As illustrated, the curriculum studies revealed that specific groups of stakeholders and professionals in the field could indeed come to a fair amount of consensus about what good teachers should know and do and that their ideas could be reported in the form of recommendations with identifiable indicators. It is important to note that there were also, of course, dissenters during this time. Different groups did not always agree with one another, so the notion of “consensus” was always contested.

As our examples reveal, however, what was recommended as a result of the early curriculum studies was too general to be of direct use to educators and so complex (and some would say, trivial) that it was impossible to implement and track. As the next section of this chapter reveals, in the years following the curriculum studies (and today in the early years of the 2000s), there were caustic attacks on teaching and teacher education, charging anti-intellectualism and myopic viewpoints held by the teachers in public schools. Educators were criticized for sharing a collective allegiance to the monolithic doctrine of progressivism (e.g. Bestor, 1953; Lynd, 1953; Smith, 1954), and there were calls for a new curriculum for teacher education, rooted in the liberal arts and sciences rather than the “mere vocational skills of pedagogy” (1953, p. 142). That there was tension—even contradiction—between the criticism of teacher education as too progressive and, simultaneously, the criticism that teacher education was too vocationalist reflects enduring disagreements within the field as well as disagreements between insiders and outside critics of the profession. This also reflects the fact that how the “problem” of teacher education was constructed and studied was continuously contested during the long history of research on teacher education.

TEACHER EDUCATION AS A TRAINING PROBLEM: LATE 1950s TO EARLY 1980s

The history of research on teacher education since World War II has been characterized by a recurring pattern: A confluence of events and/or blue-ribbon reports charges that the schools are in trouble and teachers are failing. Teacher preparation is condemned by both internal and external critics for its lack of intellectual rigor, standards, arrangements, research base, and/or failure to achieve positive results in schools. There are many calls for reform (that may be, but often are not, research-based), including calls for stronger and better-funded research. New initiatives are implemented that may or may not have lasting value, and new research programs develop with and without funding. This pattern was clear throughout the period of the 1950s to the early 1980s, when teacher education was defined primarily as a training problem.
Political, professional and policy contexts

The 1957 launch of Sputnik by the Soviets exacerbated already existing public concerns about the quality of the schools following World War II. Public education was intensely criticized for having become “soft” and “mediocre” (Lagemann, 2000, p. 159) and for emphasizing students’ interests and life adjustment over rigor and excellence.

Not surprisingly, public perceptions of school failure were linked to similar conclusions about the failure of the “educationists” who were preparing the nation’s teachers. Arthur Bestor (1953), for example, declared that educationists were making the schools into an “educational wasteland.” James Conant’s (1963) two-year study of teacher preparation concluded that the “science of education” had not yet come of age and that educational requirements for teachers were generally low. He recommended more liberal arts and humanities and less pedagogy and methods. Considerably more damning, Koerner’s (1963) study of the “mis-education” of American teachers concluded that education faculty were intellectually inferior and that the evidence regarding the value of teacher preparation was weak, if not non-existent.

Notwithstanding these critiques, new federal support programs for teacher training and recruitment were developed in the 1960s and 1970s. The Teacher Corps was enacted in 1965 as part of Title V of the Higher Education Act to address teacher shortages, particularly in high poverty areas. The Education Professions Development Act of 1967 was intended to improve educator recruitment and training. Concern about the failure of the nation’s teachers coupled with new federally-supported programs (Earley & Schneider, 1996) shaped the dominant research agenda on teacher training that emerged during this time period.

Constructing teacher education as a training problem

During this period, process-product research on teaching became prominent; this program of research had the goal of developing “the scientific basis for the art of teaching” (Gage, 1978) by specifying teacher behaviors correlated with student achievement and applying them as treatments to classroom situations. Research on teacher education also emerged as an identifiable program of empirical study. The federal research and development centers, the regional education laboratories, and large research programs played major roles in developing new lines of research on teacher education. The agenda of the University of Texas (Austin) R&D Center for Teacher Education, for example, focused on developing technologies for the training of teachers and analyzing the conditions under which these technologies were effective (Freiberg & Waxman, 1990), a line of research which was linked to the Competency Based Teacher Education movement of the 1970s (Urban, 1990).

Generally speaking, the intention of the research during this time was “answer[ing] the question of how the behavior of an individual in preparation for teaching can be made to conform to acceptable patterns” (Smith, 1971, p. 2), or, similarly, “optimiz[ing] that portion of teacher work success attributable to teacher preparation” (Turner, 1975, p. 87). The assumptions underlying “teacher education as training” mirrored the assumptions of the process-product research on teaching generally: teacher training was regarded as a technical transmission activity, teacher training and teacher behavior were assumed to be related to one another in a linear way, and training was taken to be the starting point with teacher behavior the endpoint of teacher education. With the training model, researchers concentrated on teacher rather than pupil outcomes, usually in the form of classroom behaviors. The target behaviors for prospective teachers were assumed
to be correlated with pupils’ achievement, based on the process-produce and other research on effective teaching, and thus teacher behaviors were assumed to be a correlate or a reasonable proxy for pupil outcomes.

**Studying teacher education as a training problem**

The objective of research on teacher education as a training problem was the identification of transportable training procedures that had an impact on teacher behaviors. The independent variables of process-product research on teaching (i.e., teacher behaviors that had been shown to be effective, such as clearly stated objectives for learning or certain question-asking techniques) became the dependent variables in research on teacher preparation. Teacher training procedures themselves (i.e., various procedures for training teachers to exhibit these behaviors, such as microteaching, lecture, demonstration with and without feedback) were the independent variables. The preferred method was experimental design, featuring a control and one or more treatment groups of prospective teachers who received different training, based on the presence, absence or combination of specific training techniques.

A number of research reviews were published during this time (Cyphert & Spaights, 1964; Denemark & Macdonald, 1967; Haberman & Stinnett, 1973; Hodenfield & Stinnett, 1961; Turner, 1975; Wilk et al., 1967), but the definitive synthesis of the period was the chapter on teacher education research by University of Texas, Austin, researchers, Peck and Tucker (1973) in the second *Handbook of Research on Teaching* (Travers, 1973). Peck and Tucker concluded that a “quantum leap” (p. 941) had occurred in the quality and reporting of research on teacher education between 1963 and 1965 due in part to increased federal funding for research. Based on a synthesis of “experimental research on the process of teacher education” (p. 942), they concluded that prospective teachers could learn to master specific teaching behaviors during the pre-service program using a “systems approach” or “instructional design” training procedures (p. 943).

Although the training research was dominant during this time, it was not without critics. Major critiques suggested that: the empirical base for specific teaching behaviors was itself quite thin (Haberman & Stinnett, 1973); the empirical-analytic paradigm was inadequate, uncritical, and unhelpful in improving teacher education (Popkewitz et al., 1979); and, there were major obstacles to establishing causal relationships between teacher preparation and performance given the many intervening variables and the long time lag between teacher training and later school outcomes (Turner, 1971).

Despite the critiques, training was the dominant approach to research on teacher education until it ebbed in influence by the mid-1980s when researchers became more interested in studying teacher education as a “learning problem.” This is described and analyzed below.

**Studying teacher training: two examples**

Below we describe in some detail two examples of research on teacher education, conceptualized and studied as a training problem. The first was part of a much larger program of research on teacher training using the strategy of “microteaching,” which was developed at Stanford University during the 1960s and 1970s, and was highly visible in the teacher education research and practice community. The second is an individual study of the impact on pupils’ learning of training prospective teachers to perform certain teaching competencies derived from the research on effective teaching. These examples,
each of which illustrates some of the major characteristics of studies of teacher education
during this period, provide an avenue for fleshing out this approach to research.

Along with its versions and variants, the teacher education technique of microteaching
may well have the distinction of being the most “studied” teacher training strategy of all
time. Intended for use in training prospective teachers to perform discrete teaching skills,
microteaching was first developed and applied as a combined training and diagnostic tool
during Stanford’s teacher intern program in the early 1960s (Allen, 1967; Gage, 1978;
Perlberg, 1987). According to Allen (1967), who was the chief architect of the technique
and of the research on it, “microteaching [was] a scaled-down teaching encounter that serve[d] three purposes: (1) as a preliminary experience and practice in teaching, (2) as a
research vehicle to explore training effects under controlled conditions, and (3) as an
inservice training instrument for experienced teachers” (p. 2). Allen elaborated on micro-
teaching as a training technique as follows:

the technique allows teachers to apply clearly defined teaching skills to carefully
prepared lessons in a planned series of five to ten minute encounters with a small
group of real students, often with an opportunity to observe the results on videotape.
Its distinction lies in the opportunity it provides teachers for immediate and indi-
vidual diagnostic evaluation of teacher performance by colleagues, supervisors, and
participating students and for measuring progress in specific teaching techniques.

Allen’s (1967) report on the technique was published following the fourth microteaching
clinic at Stanford and listed the discrete teaching skills the clinic aimed to teach to
prospective teachers: reinforcement, varying the stimulus, illustrating and using
examples, using student-initiated questions, and presentation skills such as set induction,
lecturing, the use of audiovisuals, and closure.

The report also detailed the teach-reteach cycle, which had been presented to 145
teacher interns at the clinic: (1) teach for 5 minutes; (2) critique for 10 minutes; (3) break
for 15 minutes so the intern could plan for changes in the re-taught lesson; (4) reteach a
different group of students for 5 minutes; and (5) critique for 10 minutes. Using the
Stanford Teacher Competence Appraisal Guide (a thirteen item, seven interval, forced-
choice scale), both the students taught by the intern and the supervisors who were over-
seeing the intern rated the intern’s performance at the conclusion of each phase. One-way
multivariate analysis of variance was performed, which revealed statistically significant
improvements between the first and final “diagnostics” (p. 20) for the interns.

Although Allen’s report praised microteaching, it also indicated that the data revealed
that students’ ratings were a more accurate measure of interns’ behavioral change than
were the supervisors’ ratings. The report also called for further development and more
intense training in the use of the Appraisal Guide with more focus on the exact technical
skills that were being taught in the micro-teaching clinic. These were subsequently
developed.

In a review of research on the pedagogy of teacher education, Grossman (2005) points
out that the research on microteaching is similar in many ways to research on the
effectiveness of other laboratory experiences in teacher training (e.g. Copeland, 1982;
McIntyre et al., 1996; Metcalf et al., 1996; Vare, 1994; Wilkinson, 1996; Winitzky &
Arends, 1991). However, although researchers have investigated microteaching
from a number of different angles to tease out the effects of subject matter, grade level,
forms of feedback, and various models, Grossman concluded, as did MacLeod (1987)
almost two decades earlier, that, given the lack of reliability and validity analyses of the
instruments and existing discrepancies between students’ and supervisors’ appraisals and other technical issues, few definitive conclusions could be drawn regarding the effects and effectiveness of microteaching. From a historical perspective, it is also worth noting that although the technique of microteaching became a subject of national attention in teacher training discussions during the late 1960s and the 1970s (Copeland, 1973; Kallenbach & Gall, 1969), it had virtually disappeared by the early 1980s (Lucas, 1999) when teacher education began to be defined as a learning problem, and there was much less interest in training strategies.

Our second example of research on teacher education, conceptualized and studied as a training problem, is Eva Baker’s (1969) study of the impact on students’ performance of teachers’ use of particular instructional principles. Conducted during the late 1960s, this study occurred in the context of Competency-Based Teacher Education (CBTE), a movement to conceptualize teachers’ roles and functions in terms of particular skills or “competencies.” Underlying CBTE was the assumption that ensuring that teacher candidates obtained “mastery” of specific pre-determined teaching competencies was more important than specifying the coursework they should complete.

Despite the push for CBTE, Baker found that there was little empirical research that had actually investigated the relationship between teachers’ classroom behaviors in keeping with the CBTE competencies and behavioral changes in their students. She hypothesized that teachers’ use of certain principles extrapolated from educational psychology courses and also required in a teacher education program would be positively related to the performance gains of students. Forty Peace Corps volunteers, who were in training to be teachers, participated in the study. The independent variables were prospective teachers’ use of five teaching principles or practices (i.e. appropriate practice, individual differentiation, perceived purposes, graduated sequence, and knowledge of results) that were assumed to be effective teaching strategies. Each prospective teacher was given a chance to practice and then present lesson plans that demonstrated these principles to a group of students and observers. Four trained observers recorded instances of the instructional use of these principles. The dependent variable was pupil gain in achievement, measured by a 15-minute multiple-choice test administered as a pre- and post-test of students’ knowledge. Analysis revealed that the prospective teachers’ use of three of the five principles was statistically significant in terms of pupils’ achievement gains: (1) appropriate practice, (2) individual differentiation, and (3) knowledge of results.

As these two examples reveal, research on teacher education as a training problem assumed that much of the complexity of teaching could be broken down into simpler, more easily trainable skills and techniques. The idea was that researchers who were studying teaching could empirically identify and label those teaching behaviors and skills that produced desirable pupil behaviors or increased pupil achievement. Then researchers who were studying teacher education could develop and test with experimental trials, specific training protocols and techniques that were most effective in teacher preparation programs. Use of these protocols and techniques could then be used across programs and at the preservice and inservice levels to help teachers achieve mastery of effective teaching behaviors.

The value of studying teacher education as a training problem

To their credit, those who carried out the training research in the 1960s and 1970s were attempting to develop and disseminate what, in the parlance of contemporary policy, might be called evidence-based practice. That is, they were developing a body of empirical research about how to produce effective teachers so that decisions could be
empirically rather than normatively based. This is precisely what is called for in the early 2000s by critics of collegiate teacher preparation who argue that there is little compelling evidence about the most effective approaches to teacher preparation. The training research revealed that prospective teachers could indeed be trained to exhibit targeted behaviors and that some training techniques were more effective than others. Assuming that teaching is in part a technical activity, it may well be that research on training can be used to establish evidence-based teacher preparation practices for some of the routine and technical tasks of teaching, such as certain aspects of classroom management and organization.

As the next two sections of this chapter reveal, however, the training research did not connect the technical aspects of teaching to its many intellectual and decision-making aspects nor did it account for how teachers’ knowledge, beliefs and prior experiences mediated their behavior in classrooms. Furthermore, the training research did not acknowledge the complex cultures of classrooms and schools or the influence of the policy and accountability contexts in which teachers’ work is embedded. Last but definitely not least in light of today’s policy context, for the most part, the training studies did not connect teacher candidate training directly to pupil learning outcomes.

TEACHER EDUCATION AS LEARNING PROBLEM: EARLY 1980s TO EARLY 2000s

During the 20 years following the training period, the pattern of critique and reform that had shaped teacher education research during the previous decades continued. Concerns about the public schools surfaced again in the 1980s, followed by critique of teacher preparation, reform of programs, and development of new lines of research.

Political, professional and policy contexts

As the 1980s began, the dire predictions of A Nation At Risk (National Commission on Excellence in Education, 1983) triggered many reforms. The Task Force on Teaching as a Profession of the Carnegie Forum on Education and the Economy (1986) called for a professionalized teaching force prepared to help redesign the schools, which would require role differentiation among teachers—with certification for some from the newly-envisioned National Board for Professional Teaching Standards (1988).

The Holmes Group report (Holmes Group, 1986) called for undergraduate liberal arts and graduate level professional preparation, teaching career ladders, high entry standards, and professional development schools linking schools of education with K-12 schools. The National Network for Educational Renewal (NNER), founded in 1986 to extend the work of the Center for Educational Renewal (Goodlad, 1990; Goodlad et al., 1990), worked from the premise that school improvement and teacher education renewal should proceed in partnership (Patterson et al., 1999).

Committed to the idea of a professional teaching force, many researchers and organizations worked to codify the professional knowledge base (e.g. Gardner, 1989; Murray, 1996; Richardson-Koehler, 1987; Shulman, 1986a). NCATE’s new standards focused on how the curriculum incorporated the professional knowledge base (Christensen, 1996), and a series of RAND studies suggested that well-prepared teachers were more effective than those without professional preparation (Darling-Hammond, 1984, 1988; Darling-Hammond & Berry, 1987; Wise, 1988). Meanwhile, Goodlad’s (1990) study of teacher education institutions called for more coherent programs and teachers prepared to meet the challenges of a changing society.
Goodlad, the Holmes Group, the Carnegie Task Force and other reformers both inside and outside the profession, advocated teacher education reform linked to the needs of the nation and to school reform and renewal. All of these assumed that a well-educated professional teacher, who was engaged in ongoing learning, was the linchpin.

**Constructing teacher education as a learning problem**

During the 1980s and into the 2000s, research on teacher education was influenced by the professionalization agenda, an expanded array of research perspectives (Erickson, 1986; Lagemann, 2000), and emerging research programs on teaching and teacher knowledge, such as the program at Michigan State University spearheaded by Judith Lanier and Lee Shulman in the late 1970s. During this time, the concepts and language of “learning to teach” (Feiman-Nemser, 1983) more or less replaced the language of “teacher training.” Researchers studied the knowledge, attitudes and beliefs of prospective teachers as they began formal preparation; how these changed over time; the kinds and sources of knowledge teachers needed to teach well; how teachers learned that knowledge; and, how teachers interpreted their experiences in courses, fieldwork and other contexts.

To a great extent, constructing teacher education as a learning problem meant explicitly rejecting the technical view of teaching and the training view of teacher education that had been prevalent (Lanier, 1982; Tom, 1980). Not everybody agreed of course. How to conceptualize and conduct research on teaching and teacher education was hotly debated during this period, referred to by some as “the paradigm wars” (Gage, 1989). Notwithstanding the debates, the general shift from training to learning was quite evident. Some of the research on teacher learning derived from cognitive psychology, with emphasis on teachers’ subject matter and pedagogical knowledge. Other work drew on perspectives from anthropology and sociology, with a focus on culture and its role in learning and schooling. All of these approaches presumed that teaching was a cognitive and intellectual practice that was situated, complex, and uncertain. This meant that it was important for teachers to learn how to make decisions, apply strategies differently in different situations, and reflect on their work. It is important to note, however, that differing theoretical perspectives were affiliated with quite different ideas about the impact of teacher preparation and the types of research that were most needed.

**Studying teacher education as a learning problem**

Not surprisingly and in keeping with the different disciplinary roots noted above, methods for studying teacher education as a learning problem involved multiple research questions and methods rather than adherence to a single paradigm. Although there were still studies of training, many researchers examined teachers’ attitudes, beliefs, knowledge structures, predispositions, perceptions and understandings as well as their intellectual, social and organizational contexts. A major program of research also developed about how teachers learned to teach for diversity (e.g. Bennett, 1995; Ladson-Billings, 1995; Zeichner, 1993). In addition to new research perspectives from the social sciences and humanities, there were also new investigators of teacher education, including teacher educators who studied their own practices (e.g. Hamilton, 1998; Loughran, 1998) and studies from critical and feminist perspectives (e.g. Britzman, 1991; Gore, 1993; Ladson-Billings, 1999; Luke, 1992).

During the 1980s and 1990s, there were several major syntheses and short reviews of research on teacher education (e.g. Koehler, 1985; Richardson & Placier, 2001). Reflecting the evolving shift from training to learning, Lanier and Little’s (1986) chapter in the
third *Handbook of Research on Teaching* excluded experimental research and instead synthesized interdisciplinary research. They concluded that teacher preparation was pervaded by conservatism and a student body expecting a technical model. Houston’s (1990) *Handbook of Research on Teacher Education* synthesized research in all the areas in Lanier and Little’s review in addition to teacher education governance, models, evaluation, and curriculum. Both Houston’s handbook and its second edition (Sikula et al., 1996) suggested that the thin research base on teacher education was the result of the low priority the nation placed on schooling and teacher education. Borko and Putnam’s synthesis (1996) focused on the psychological aspects of learning to teach, concluding it was a complex process requiring multiple knowledge bases, skills and understandings. Wideen et al.’s (1998) synthesis concluded not only that initial beliefs were difficult to change, a finding that continues to be supported in contemporary research, but also that there was a fundamental tension between teacher educators’ desire to change their students’ beliefs and prospective teachers’ desire to learn how to “do” teaching.

**Studying teacher learning: two examples**

Below we discuss two examples of research on teacher education, conceptualized and studied as a learning problem. The first, Pam Grossman’s (1990) study, was part of a larger program of research on the knowledge needed for teaching and how teachers learn to teach, particularly how they develop and use various kinds of knowledge including pedagogical content knowledge. This program of research grew out of work by Lee Shulman and colleagues that began at Michigan State University in the late 1970s and was further developed by Shulman and his students and colleagues at Stanford University in the 1980s (e.g. Grossman, 1990; Grossman et al., 1989; Wilson et al., 1987). Grossman’s research used a case study method to investigate both the nature of pedagogical content knowledge among beginning English teachers and the role of subject-specific teacher education coursework in contributing to graduates’ knowledge and beliefs about teaching English. She studied six first-year English teachers from the San Francisco Bay area including three who had graduated from the same teacher education program and three who entered teaching without formal training. Data collection included semi-structured interviews and multiple classroom observations. Analysis involved coding of all data within each case as well as cross-case analyses.

Grossman’s research suggested that those with a teacher education background were flexible, open to innovative methods, and better able to comprehend students’ perspectives. Those without such experience tended to rely on teaching techniques borrowed from undergraduate and graduate courses or on memories from their own K-12 schooling. This analysis suggested that a coherent and consistent vision of teaching and learning was important. Grossman suggested that four general features of a teacher education program seemed to contribute to the beginning teachers’ learning included:

- a coherent vision of teaching and learning, organized around the specific subject matter to be taught; a collaborative relationship among professor, supervisors, and students, in which prospective teachers helped construct their evolving knowledge concerning the teaching of English for which they could feel a sense of ownership; the existence of necessary support, or “scaffolding” for prospective teachers as they acquired skills and pedagogical perspective for teaching and developed a reflective stance toward practice; and a developmental perspective on learning to teach, in which the curriculum provided the knowledge and skills appropriate for both the current and future needs and concerns of prospective teachers.

(p. 139)
Our second example (Laframboise & Griffith, 1997) of studying teacher education as a learning problem, was conducted by a pair of researchers who were part of a group of teacher educators at the University of South Florida who worked with teacher candidates at a professional development school. Their study focused on how and what teacher candidates learned about culture and cultural conflict by reading literature cases. More specifically they used teaching cases or problem-based stories of teaching practice written by either a teacher or an observer who collaborated with the classroom teacher about teaching events in his or her classroom. The intention of these cases was to help preservice teachers reflect and problem solve with the goal of integrating information from course readings, observations in other classrooms, and course discussions that highlighted multiple perspectives, enabling students in a teacher education course “to view themselves as part of a culturally diverse society, to confront their own subjectivity, and to examine critical issues related to children and schooling” (p. 369). Additionally, the researchers were interested in how undergraduate students made meaning from instances of cultural conflict that were portrayed in juvenile novels and how they used that information to develop appropriate practice for case-based instruction in teacher education courses.

Twenty-two preservice teachers (four White males and 18 White females, ranging in age from 20 to 40) in their first semester of a five-semester undergraduate teacher education program were studied while they participated in an early field experience and site-based course at a PDS. The PDS was a K-5 school in a rural section of a large school district serving a population that was 24 percent White, 10 percent African American, and 66 percent either Mexican or Mexican-American.

Data sources included audio-taped discussions centered around problem-centered stories (teaching cases) and juvenile novels as well as the interns’ written work, including literature logs, postwriting, and write-ups from classroom observations. Data were coded using Olneck’s (2001) categories of cultural discontinuity—gender, student-to-student, student-to-teacher, student-to-family and cultural community, and student-to-community outside the cultural group—and six categories of interns’ meaning making that emerged—paraphrasing, connecting to own knowledge, comparing, inferring, critiquing, and connecting to course content. Researchers concluded that students were able to correctly identify many sources of cultural discontinuity for characters in a book, to make connections to their own experiences, and to think critically about issues of cultural conflict. In most cases, stating and paraphrasing the information from the text was the initial step in discussions and writing, but researchers found this was often not sufficient to make sense of discontinuities. Discussion groups appeared to need someone to act as a challenger, to force the thinking of the group past literal levels, and to help students examine their own subjectivities. The researchers also concluded that preservice teachers needed to confront issues of diversity in ways that encouraged reflection and allowed students to have vicarious experiences of people and situations beyond the context of their immediate lives. The literature case discussions created an environment where students could examine their own values and attitudes, express divergent views, and learn reflective practices.

The value of studying teacher education as a learning problem

In his 1986 review of paradigms and research programs on teaching, Shulman (1986a) suggested that what was missing from the research on teaching was research on how teachers understood and used subject matter knowledge. Since that time, however, research on teachers’ cognition, knowledge use, beliefs, and experiences has been so
plentiful that some scholars (e.g. Wilson et al., 2001) have suggested that what is now missing is research that connects teachers’ knowledge and beliefs to pupils’ learning and other outcomes. Even Shulman (2002) has acknowledged this limitation, concluding recently that research on teachers’ knowledge and use “reflects the theoretical importance of the three Cs of content, cognition and context [but] continued to ignore a fourth C, consequences for students” (p. 251). This assessment of the research on teaching also applies to research on teacher education. When teacher education is primarily constructed and studied as a learning problem, understanding teachers’ knowledge and beliefs is considered an important research purpose in its own right and there is often little or no attention to pupil achievement or to the link between teachers’ knowledge and beliefs and pupils’ learning and other desirable educational outcomes.

As we argue in the next section, during the late 1990s and into the 2000s, research on teacher education shifted from teacher knowledge and learning issues to educational policy issues with a focus on the outcomes and consequences of teacher education policies and practices. It is important to note that in many policy-related critiques, much of the research on knowledge and beliefs is not regarded as particularly useful because it does not examine causal questions or make the link to pupil achievement and thus, it is claimed, has limited implications for policy.

TEACHER EDUCATION AS A POLICY PROBLEM: MID-1990s TO PRESENT

From the mid-1990s and into the 2000s, the focus on high standards and accountability was intense. The emphasis in research on teacher education shifted from learning to policy, and the problem of teacher education was constructed and studied as a matter of specifying the policies and practices warranted by empirical evidence and cost-benefit analyses linked to pupils’ achievement.

Political, professional, and policy contexts

By the mid-1990s, the shifting global economy coupled with the continuing achievement gap had created an urgency about improving education. As in previous eras, these concerns were linked to public demands for reforms in teaching and teacher education. In 1994 the Rockefeller Foundation and the Carnegie Corporation supported the new National Commission on Teaching and America’s Future (NCTAF), which asserted that teaching and teacher education mattered more than anything else in improving school achievement (National Commission on Teaching & America’s Future, 1996). Along with other professional organizations, NCTAF aimed to improve teacher preparation through systematic professionalization and high standards across the professional lifespan. In addition, the American Council on Education’s President’s Task Force on Teacher Education (1999) promoted increased higher education responsibility for teacher preparation.

Meanwhile conservative foundations advocated deregulation of teacher education and redirection of public authority for teacher quality by significantly reducing college- and university-based teacher education and state-level certification bureaucracies. The Fordham Foundation (Kanstoroom & Finn, 1999) and others called for market-based reforms including alternate routes that focused only on results.

In nearly every state, new curricular frameworks were implemented coupled with new standards for K-12 student achievement and new standardized tests. The goal was to
hold schools accountable to internationally competitive standards and assessments (National Education Goals Panel, 1997). Between 1987 and 1998, the number of states requiring tests for entry into teaching greatly increased and became more standardized (SRI International, 2000), and based on legislation enacted in 1998, institutions and states were required to report annually to the government on the credentials of all teachers they certified.

CONSTRUCTING TEACHER EDUCATION AS A POLICY PROBLEM

During this period, advocates of competing agendas for the reform of teacher education claimed to have an empirical research base. One result of highly publicized and politicized debates was to draw sharp attention to research on teacher education. With more and higher level policy makers working on policies related to teaching and teacher education, education came to be constructed primarily as a policy problem rather than as a curriculum, training, or learning problem as the previous decades had done.

The assumption behind constructing teacher education as a policy problem is that one important way policy makers can meet the challenges of providing a high-quality teaching force is by manipulating those broad aspects of teacher preparation (e.g. teacher tests, subject matter requirements, entry routes) most likely to affect pupil achievement. Although the intention here is to use empirical research to identify those aspects most likely to boost achievement, as is argued below, the research to support any particular policy is not necessarily straightforward. Several of the most debated research syntheses during this time examined the impact of teacher education as part of analyses of state-level policies regarding certification, licensure, teacher tests and other accountability mechanisms (Ballou & Podgursky, 2000; Darling-Hammond, 2000b). Some used econometric models and techniques, including cost-benefit and other analyses, to draw conclusions about the impact of school resources, including teacher qualifications (e.g. Hanushek, 1997). Others examined the research base for state or institutional policies regarding teacher requirements such as subject matter preparation, coursework and field experiences (Allen, 2003; Rice, 2003). Underlying the construction and study of teacher education as a policy problem is the assumption that empirical evidence linking teacher preparation and desirable student outcomes can and should shape policies and practices regarding teacher preparation.

STUDYING TEACHER EDUCATION AS A POLICY PROBLEM

As noted above, many research syntheses since 2000 have constructed teacher education as a policy problem, but reached different conclusions about what the evidence says. Darling-Hammond’s (2000a, 2000b, 2002) analyses of evidence related to teacher quality and achievement, for example, concluded that teacher preparation and certification, regarded as important aspects of a cluster of variables that comprise teachers’ qualifications, contributed at least as much as, if not more than, other variables to educational outcomes including teacher effectiveness and students’ achievement. In contrast, a second group of syntheses and responses (e.g. Abell Foundation, 2001a, 2001b; Ballou & Podgursky, 2000; Whitehurst, 2002) concluded that while there was evidence that teachers’ verbal ability and subject matter knowledge had an impact on pupil achievement, there was little evidence to support collegiate teacher
preparation, the study of pedagogy, teacher certification, or program approval and accreditation.

A third group of syntheses (e.g. Allen, 2003; Cochran-Smith & Zeichner, 2005; Lauer, 2001; Rice, 2003; Wilson et al., 2001) concluded that although there was some evidence that teacher preparation and certification had a positive impact on educational outcomes in some content areas and at certain school levels, the research base related to teacher preparation as policy was generally neither deep nor robust. Results were mixed in many areas, inconclusive in others, and there was virtually no reliable research in still other areas. These syntheses called for greater investments in research on teacher preparation and in developing qualified teachers. Although their language and emphases differ, the syntheses in this third group were generally consistent in their conclusion that although the teacher education research base about outcomes was thin, but there was also no evidence supporting full-scale elimination of credentialing requirements and no conclusive evidence about the best structures or pathways for preparing teachers.

**Studying teacher education policy: two examples**

Below we describe in some detail two examples of research on teacher education, conceptualized and studied as a policy problem. The first, a study sponsored in part by the Carnegie Corporation of America and conducted by the Mathematica Policy Research, Inc., compared the effectiveness of teachers prepared in the “Teach for America” (TFA) teacher recruitment program with that of non-TFA teachers (Decker et al., 2004). The second example is somewhat similar—using mixed research methods, included a value-added model, this study examined six pathways into teaching in the New York Public Schools including prospective teachers entering via the Teach for America (TFA) program and the Teaching Fellows Program (Boyd et al., 2005).

TFA has been a hot-button issue among teacher educators and policy makers since its inception in 1989. Indeed in many contentious debates, TFA has been constructed as both the poster child for alternative routes into teaching (even though it is technically not an alternative route, but a teacher recruitment and initial training program) and a major battleground for larger discussions about who should teach, what they should know, how and where they should be prepared, and who should decide. TFA is a publicly- and privately-funded organization that has established a national “corps” of recent college graduates with a variety of academic majors, recruited at Ivy League and other highly academically-rated colleges and universities across the nation. TFA volunteers make a commitment to teach in hard-to-staff urban and rural public schools for a minimum of two years. The organization’s mission is to contribute to the elimination of educational inequity by recruiting into teaching in low-income schools some of the nation’s most promising future leaders. The idea is that TFA alumni work for change from within education and from other sectors to ensure that all children have opportunities to learn (Smith, 2005).

A team of researchers from Mathematica Policy Research (Decker et al., 2004) compared the reading and mathematics test scores of pupils taught by TFA teachers with those taught by non-TFA teachers to address the question, “Do TFA teachers improve (or at least not harm) student outcomes relative to what would have happened in their absence?” (p. ix). The test scores of pupils randomly assigned to TFA teachers and non-TFA teachers (with non-TFA teachers defined as all those who were never part of TFA, including traditionally certified, alternately certified, and uncertified teachers) were compared, as were test scores of pupils with novice TFA and novice non-TFA teachers (with novices defined as teachers in the first three years of teaching).
Following a pilot study in Baltimore, the investigation focused on 1800 pupils in grades 1–5 in 17 schools—all of which served economically disadvantaged students and faced substantial teacher shortages—in Chicago, Los Angeles, Houston, New Orleans, and the Mississippi Delta. The schools were chosen to be broadly representative of the schools where TFA teachers were placed at the time of the study, and the pupils were randomly assigned to classrooms with TFA teachers and control group teachers. Measures of student achievement were the Iowa Tests of Basic Skills in reading and mathematics. A baseline achievement test was administered in the fall, and a follow-up test was administered in the spring to each of the classes with over 90 percent of students completing both tests. Researchers found significant differences in mathematics, with the average scores of students taught by non-TFA teachers falling into the 15th percentile in the fall and remaining in the 15th percentile in the spring, while average scores of students with TFA teachers falling into the 14th percentile in the fall and increasing to the 17th percentile in the spring. Differences were also significant for students in different grades and those with differing ethnic backgrounds as well as for novice teachers in the two groups. In reading, students taught by TFA and non-TFA teachers experienced the same average growth rate—one percentile point during the school year.

Our second example of teacher education as a policy problem is a study by Boyd et al. (2005) examining the impact of pathways into teaching on the teacher workforce in the New York City Schools where many different entry routes are in place, including the Teaching Fellows Program and Teach For America (TFA). The Fellows Program (2006), described as “the largest alternative certification program in the country,” aims to attract mid-career professionals, recent college graduates, and retirees to teach in under-performing schools. TFA (2006) is a national corps of top recent college graduates, as described in the Decker example above.

Boyd and colleagues (2005) identified six pathway into teaching in NYC: (1) college-recommended; (2) individual evaluation; (3) Teaching Fellows Program; (4) Teach For America; (5) temporary license; and (6) other. The study addressed two questions: (1) how the achievement gains of students differ by the teacher pathway; and more specifically, (2) whether students of teachers who enter the classroom through alternative routes with reduced coursework and field experiences achieve gains that are higher or lower than they would have if taught by traditionally certified or temporary licensed teachers? The student database (students in grades 3–8 between 1998 and 2004) included demographic and exam information. The teacher database included demographics, test performance, and pathway. Using a value-added model for analysis, the researchers examined trends in teachers by pathway, characteristics of classes, student achievement, effects of pathways relative to achievement, and teacher attrition.

Findings were reported relative to supply, teachers’ general knowledge, teaching at the elementary and middle school levels, and rates of attrition: The composition and overall supply of teachers in NYC changed as a result of certification requirements that included alternative pathways, largely eliminating uncertified teachers. Many teachers in alternative pathways had strong academic training and performed well on tests of general knowledge. There was some evidence that elementary teachers in alternate routes did not teach mathematics or English Language Arts as well as teachers from the college-recommended path during their first year. However, their mathematics teaching improved differentially between their first and second years and was approximately equivalent to that of the college-recommended teachers during the second year. Alternative route middle school teachers did better than alternate route elementary teachers. TFA members did a better job of teaching mathematics to middle school students than either temporary license or college-recommended teachers during their first year, while Fellows performed as
well as these teachers. By their third year of experience Fellows out-performed college-recommended and temporary licensed mathematics teachers. But results for English Language Arts in middle school were not as strong; the students of both Fellows and TFA teachers in their first year had lower achievement gains than college-recommended or temporary licensed teachers. Fellows showed differentially strong improvement in teaching between their second and third years.

In terms of attrition, the results from this study indicated that the differences in attrition rates across pathways were significant and meaningful. The attrition rate (when controlled for fixed school effects) of Fellows was roughly comparable to college-recommended teachers after two years but exceeded them after three or four years. Those entering through TFA also were relatively more likely to return in their second year. The retention of TFA teachers beyond the second year fell off dramatically, both relative to the traditional routes and the Fellows pathway. This study predicted that after four years fewer than 20 percent of TFA teachers would remain teaching in these schools.

In conclusion, Boyd and colleagues suggested that teachers’ varying experiences prior to beginning as the teacher of record and differing coursework might have influenced outcomes. They also highlighted policy questions not addressed such as the attributes of preparation that are most important in increasing student achievement and how the size and composition of the college-recommended pool of teachers would change if financial incentives or reduced tuition towards a masters degree were available.

The value of studying teacher education as a policy problem

The essence of studying teacher education as a policy problem is to identify which broad parameters of teacher education policy that can be controlled by policy makers are most likely to lead to desirable student outcomes. In the midst of the current accountability context, it now seems “obvious” that state and institutional policy decisions should be driven, at least in part, by empirical evidence. But there are also many questions about the bases of comparisons in policy studies (e.g. Wilson & Youngs, 2005; Zeichner, 2005a). Although we need to invest in the capacity to conduct rigorous research on teacher education as a policy problem, we also need to acknowledge its limitations. The aspects of teacher education studied from this perspective are often “crude quantifiable indicators” (Kennedy, 1999, p. 85) that cannot be used to make meaningful distinctions across institutions, pathways, and programs. In addition, policy studies do not account for the contexts and cultures of K-12 schools or for how these support or constrain teachers’ abilities to apply knowledge and skills.

Finally, it is worth noting that when teacher education is constructed as a policy problem, the focus is almost always on pupil achievement, defined as test scores, as the most important educational outcome. While this is important, it is not the only goal of preparation programs. Such outcomes as pupils’ social and emotional growth and their preparedness to live in a democratic society and engage in civic discourse are also important as are goals such as teacher placement and retention in hard-to-staff schools and as advocates for educational equity.
RESEARCHING TEACHER EDUCATION IN CHANGING TIMES:
DIRECTIONS FORWARD

We have suggested that the history of research on teacher education over the last century can be explained at least in part by identifying how “the problem” of teacher education is constructed and how that problem is studied, analyzed and interpreted. Different ways of constructing and studying teacher education—as a curriculum problem, a training problem, a learning problem, or a policy problem—are influenced by the changing political, professional and policy contexts of the times. Particularly important are public concerns and policies about teachers and schooling linked to larger economic and social issues, internal and external critiques of teacher education coupled with demands for reform, and new directions in educational research. It is also important to acknowledge that the quality of some published research on teacher education is poor. This judgment holds across research paradigms and methods. As in any field, poor quality research contributes to the impression that the research base is weak.

It is also important, however, to note that some of those who have concluded that the research base for teacher education is weak have done so because they were interested in a particular construction of the “problem” of teacher education about which there has been little research, even though large amounts of worthwhile research have been conducted on different constructions of the problem. Some reviewers have reached different conclusions about the research base because they worked from different constructions of the problem. This means that simply asking a different question about the quality and depth of the research base on teacher education can produce a different answer (Cochran-Smith, 2004). At other times, however, reviewers have asked similar questions but worked from differing assumptions about what counted as research, what levels of data aggregation were appropriate, or what educational outcomes mattered.

For example, although Peck and Tucker’s (1973) review (discussed in the section on “training”) focused exclusively on experimental research on the instructional methods used in teacher education, Whitehurst’s brief review in 2002 (noted in the section on teacher education as a policy problem) complained that experimental research methods had not yet been discovered in research on teacher education. Peck and Tucker were working from the perspective that teacher education was a training problem and thus reviewed experimentally-verifiable techniques for training teachers to perform certain behaviors assumed to be effective. On the other hand, Whitehurst, who worked from a construction of teacher education as a policy problem, was looking for causal or correlational evidence about the impact of teacher preparation policies on pupils’ achievement that could guide policymakers’ decisions. The contrasts in the conclusions of these and other syntheses about the strength and depth of the research base for teacher education reflect both historical and contemporary issues.

Some researchers assume that teachers’ learning (e.g. enhanced subject matter knowledge, changes in beliefs and attitudes about diverse populations, increased skill) is a justifiable outcome of teacher preparation because of its impact on instructional decisions, relationships with pupils and families, and quality of classroom learning opportunities. This approach is based on the premise that teachers’ knowledge frames and beliefs are filters through which teachers’ practices and decisions are made and through which they decide how to apply the various skills they have learned. The assumption is that knowledge and beliefs always mediate practice and the application of skills and thus knowledge and beliefs always influence pupils’ learning opportunities, achievement, and other educational outcomes. From this perspective, teacher learning itself is an important outcome of teacher preparation. When teacher learning is the focus
of teacher education research, it is not the case, as some have claimed, that pupils’
learning is considered unimportant. Rather the link between teachers’ learning and
pupils’ learning is not the focus of that particular line of research. Instead the link
between teacher preparation components and organizational structures, on the one
hand, and teachers’ development of knowledge, skills, and/or rethinking of beliefs and
attitudes, on the other, is the focus. One needed line of research currently is research that
examines and untangles the relationships between and among teachers’ knowledge and
beliefs, their professional skill and performance in classrooms, and their pupils’ learning.
In this chapter we have tried to make the case that historically there have been
different constructions of the problem of teacher education coupled with different
assumptions about how to study that problem. These reflect larger political, professional
and policy contexts but also help to explain some of the differences in the conclusions
of contemporary syntheses. These divergent conclusions may suggest the need for new
initiatives in teacher education research that combine various constructions of the prob-
lem of teacher education as curriculum, training, learning and policy and examine the
relationships among these.
It is also important to point out, as our analysis suggests, that some of what are
considered serious failings in the research on teacher education are more rightly under-
stood as reflections of the field’s relative youth. Empirical research on teacher education
really developed as an identifiable line of research only during the last half century. Even
if we count, as we have in this chapter, the early institutional self-studies and surveys of
normal schools and colleges and universities conducted in the 1920s and 1930s, the field
is no more than 70 to 80 years old. Some of the strengths and limitations of the research
reflect this newness. Other strengths and weaknesses reflect the priorities and viewpoints
of the time. For example, in the early and middle of the twentieth century, there was
harsh critique of the “educationists” and the “scientism” they were pursuing, particu-
larly the notion that science rather than philosophy or moral education should suggest
solutions to the problems of teacher education. In the early years of the twenty-first
century, however, science has skyrocketed in importance. It is now written into federal
law that scientific evidence ought to be the grounding for educational practice, policy and
resource allocation. Changing times have an influence on changing paradigms for
research on teacher education.
Finally, our discussion of the shift in research on teacher education from curriculum to
training to learning to policy coupled with our analysis of the value and limits of each
approach suggest that studies that link these aspects of teacher preparation could prove
worthwhile. A few initiatives in their early stages are attempting to study the impact of
teacher education policies that have built into them differing degrees and kinds of sup-
port for teachers’ learning, thus tying together the constructions of teacher education as
learning and teacher education as policy in sophisticated and intriguing new ways. As
research on teacher education continues to evolve, we will need much more sophisticated
scholarship that builds theory as well as generalizable knowledge about effectiveness.
That means we will continue to need rich and detailed case studies as well as large-scale
surveys. The emphasis needs to be on asking the important questions—and constructing
the problem of teacher education in thoughtful, appropriate ways—and then on selecting
the appropriate methods of data collection and analysis.

NOTE
1 This chapter draws on our analysis of teacher education research from the 1950s through the
2000s (Cochran-Smith & Fries, 2005a).

Critical and qualitative research in teacher education

A blues epistemology for cultural well-being and a reason for knowing

Joyce E. King
Georgia State University

Defenders of white blues are often proponents of “color-blindness” as the ultimate weapon of anti-racism, but many of these color-blind whites are really resisting the importance of consciousness of race and race matters, with all the nagging reminders of racism contained therein. They believe that by refusing to use race as a criterion for anything, they are being the ultimate non-racists, but they are actually blinding themselves to the complexity of racial issues.

Paul Garon, 1995

I think we’re at a moment now in which a blues nation has to learn from a blues people.
Cornell West, Interview with Toni Morrison, 2005

People who have no choice but to live their life in their black skins know racism when they see it. Racism is never subtle to the victim. Only White people say race doesn’t matter.
Carrie Morris, Pathways School Faculty Member, 1996

Nobody’s coming to get us . . . Nobody’s coming to get us.
Aaron Broussard, President, Jefferson Parish, Louisiana, 2005

But can you expect teachers to revolutionize the social order for the good of the community? Indeed, we must expect this very thing. The educational system of a country is worthless unless it accomplishes this very task.
Carter G. Woodson, 1933/1977

INTRODUCTION

A growing body of teacher education research documents the fact that many experienced and future teachers resist a critically transformative understanding of race and racial inequity. This resistance, which can be understood as a result of mis-education, is an ongoing challenge for the profession and for teacher education research. Emergent inquiry-based pedagogical approaches that use the knowledge traditions and lived experiences of marginalized and oppressed groups in teacher learning (and un-learning racism) with community members suggest possible ways out of this knowledge crisis. However, research on teacher education has yet to address the belief structure of race in ideologically biased school/academic knowledge and research that contributes to the mis-education of teachers, although a tradition of Black scholarship has long recognized this epistemological problem (McDaniels, 2006).
Writing nearly a century ago in 1917, for example, Black sociologist, lawyer, and historian, George Washington Ellis, pinpointed the hegemonic role of ideological knowledge in maintaining the mythology of race and perpetuating racial injustice. For Ellis “scholarly activity had to be moved from the ideological position of racism to the ideological position of democracy” for the benefit of the entire society (Childs, 1989, p. 87). A few years later, the research of another Black historian, educator, and activist scholar, Carter G. Woodson, who founded “Black History Week/Month” in 1927, showed how ideological school knowledge obstructs democratic community in the U.S. His analysis of mis-education, that is, how ideologically biased school knowledge systematically teaches whites to feel superior and Black people to feel inferior, led Woodson (1933) to call for teachers to “revolutionize the social order”.

The integrity of Black culture, including its African roots, was fundamental in these scholarly challenges that Ellis, Woodson, and others have launched to combat the hegemony of ideologically biased knowledge (Gleason, 2006; King, 1992, 1995). Scholarly defense of Black culture and heritage has been necessary, not solely to set the historical record straight on behalf of African Americans, but also as an investment in human freedom from dehumanizing supremacist ideologies. The “convergence of critical thought and action” (King, 2004, p. 351) and the inextricable connection between the general welfare of humanity and Black people’s cultural well-being are defining qualities of this Black intellectual tradition that have been carried forward in the modern discipline of Black Studies (B. Gordon, 1990, 1995). A Black Studies theoretical analysis is employed in this chapter to consider how (and how well) critical and qualitative research (and practice) in teacher education produces knowledge, understanding, and social action for racial-social justice. This hyphenated term is used in order not to lose sight of Black people’s group survival needs, that is, the “requirements for black existence,” in transformative visions of equity and democratic inclusion (Cone, 1972, p. 27).

Focus of the chapter

This chapter focuses on four inter-related genres of critical and qualitative research in teacher education with racial-social justice aims: (1) critical race theorizing, (2) whiteness studies, (3) critical ethnography, and (4) practitioner inquiry, including action research “in, on, and for” teacher education (Cochran-Smith & Lytle, 2004). The Black Studies theoretical analysis that informs the discussion of these modes of inquiry focuses analytical attention on the belief structure of race in ideologically biased knowledge in schools and academe and epistemologies and indigenous knowledge traditions from the ideological position of democracy. One example, the epistemology of the Black experience embodied in the African American blues tradition, will be used as a heuristic framework to suggest cultural well-being as a measure of what/how these modes of research can contribute to equity and democratic inclusion in education and society. It will be argued that a crisis of knowledge in teacher education research (and practice) exists because of the absence of marginalized and oppressed people’s epistemologies as a foundation of knowledge for teacher learning and for teaching. Thus, the discussion of these genres of research goes beyond a focus only on the mis-education of teachers. Rather, the emphasis also is on producing knowledge for the benefit of marginalized communities and the general society’s welfare. Several overlapping questions will illuminate this missing cultural well-being framework: (1) What/whose social vision does research honor and project? (2) Is the cultural well-being of marginalized groups a consideration? (3) What is missing in the theory and methods of these genres of inquiry, given their group survival needs, that is, the “requirements of black existence,” for example? (4) Can research
informed by the blues epistemology of the Black experience advance understanding of the interconnections among Black people’s cultural well-being, positive inter-group relations, and humanity’s general welfare?

Organization of the chapter

The chapter is divided into four parts. The first part, “Epistemologies and Knowledge Traditions for Cultural Well-Being,” introduces the Black Studies analysis of the ideology of race and the blues epistemology of the Black experience. “Decolonizing” methodology and theory articulated and used by indigenous peoples that complement the blues epistemology are also presented. The second part of the chapter, “From Critical Social Theories/Theorizing to Critical Research Methods,” briefly reviews the genealogy of critical theory and methods in the social sciences and teacher education. The research examples discussed illustrate various critical methods, including critical race theory, critical ethnography, as well as investigations of the discourse of “whiteness,” and selected feminist research approaches. The third section of the chapter, “A Continuum of Practitioner Inquiry: Learning to Teach for Social Change,” examines the use of various qualitative research methods in teacher education research—from individual narratives to ethnography to action research in community settings. The final section, “Beyond the Crisis of Knowledge in Teacher Education Research and Practice,” presents teacher education methods that incorporate community knowledge and new roles for community members that support mutually beneficial teacher learning and development.

EPISTEMOLOGIES AND KNOWLEDGE TRADITIONS FOR CULTURAL WELL-BEING

In spite of a burgeoning body of multicultural education literature (Banks & Banks, 2004; Goodwin & Swartz, 2004; McAllister & Irvine, 2000), teacher education research has produced no accepted consensus about what teachers should “know, be able to do and be like” to promote and safeguard the cultural well-being, sense of belonging, and agency of African American learners (King, 1994; Lee, 2001) or other marginalized students. Murrell (2001) offers this cogent description of “capable” urban teachers who:

. . . must be aware that there is a deep and profound violence embedded in the fabric of American popular and institutional culture that is a significant and toxic part of children’s school experience. Where there is not an anti-racist awareness and explicit pedagogy for working with African American children and families, there persists an insidious violence that even the most well-meaning teacher will be a participant in despite beliefs and values to the contrary.

(p. 75)

In this vein S. King and Castenell (2001) assert: “the task of fighting racism has to be the bottom line” if educational institutions are going to prepare “teachers with the will and the strategies to teach all children” (p. 10). Assaults on “blackness as a cultural reality,” as in the following example, is one form that racism takes (Murrell, 1997, p. 33). A student teacher related in one of my courses how a white teacher at an award-winning elementary school described the Black children in her classroom. The teacher said that there were two groups of Black children in her assigned classroom: the “black-Blacks” and the “white-Blacks.” The teacher informed her that attempting to teach the “black-Blacks”
would be a waste of time because they have “black values.” Teaching the “white-Blacks,” on the other hand, who have “white values,” would be worthwhile. The student was shocked and chagrined because she was among those credential candidates who had resisted the focus on racial inequity in the required cross-cultural communications course.

Knowledge for cultural well-being: a task for research

To combat such beliefs Murrell (2001) calls for a pedagogy “grounded in the history, traditions, and cultural heritage of African Americans” (p. 33). However, this will require re-writing academic and school knowledge (Loewen, 1995; Stevens et al., 2005; Wynter, 2006). Following are three examples of ideologically biased academic/school knowledge, including misrepresentations of slavery in textbooks and classroom discourse that contribute to the mis-education of teachers and assaults on cultural blackness. First, an ethnographic investigation in predominately white suburban middle school classrooms reveals the limits of the white teachers’ knowledge and pedagogical skills regarding teaching about the enslavement of African people and the heritage of Native Americans. Classroom discourse renders African Americans “present in the curriculum” but only as slaves, and, thus, “absent in history” (Wills et al., 2004, p. 107).

Second, in my work with teachers I ask if anyone can name the three universities that existed in West Africa before Columbus arrived in the Americas (Gao, D’jenné, and Sankoré at Timbuktu in present-day Mali). Nearly always the response is: “No.” Kincheloe (2004) reports a similar experience when he asks whether teachers have studied “the story of the European colonization of Africa and the effects of the slave trade” (p. 1). In fact, the structure of knowledge in the discipline that separates African history from American history circumscribes what teachers (and their students) can learn about Africa, slavery, and the development of U.S. society. Teachers learn little if anything concerning the vital role not just of African labor but also the sophisticated knowledge and skills African people possessed that made the nation’s development and wealth possible (Carney, 2001; King, 2006). Fragmentation of historical knowledge thus obstructs the critical understanding teachers need to explain African descent people’s continuing impoverishment given the nature and function of global capitalism—then and now (Maiga, 2005). The devastation of urban communities that has undermined traditional African American culture, community viability, and beneficial socialization practices—conditions that are portrayed as a “culture of poverty” and as culturally deficient “black-values” (Heath, 1989; King & Wilson, 1994).

A third example is the way “dysconsciousness,” the term I introduced to describe such “limited and distorted understandings” of racial inequity, is used in multicultural teacher education and critical race scholarship (King, 1991a). Though it is often cited in discussions of racism, none of these publications reference the key finding of the original study of dysconsciousness: pre-service teachers typically explained racial inequality “as a historically inevitable consequence of slavery or as a result of prejudice and discrimination” (King, 1991a, p. 138), which they also linked to slavery. None of their explanations showed any recognition of the systemic nature of racism (Duncan, 2004) or the “structural underpinnings of inequity” (Cochran-Smith et al., 2004, p. 956).

Generating forms of knowledge and effective pedagogy that teachers need to address such ideological constructions of race is a task for teacher education research. As Hilliard (2001) cautions, however, researchers have unfortunately been “following the detour of race rather than the ideology that propels it” (p. 2). In a Black Studies analysis of the ideological belief structure of race Wynter (2003, 2006) argues that racism is a logical
outcome, an effect of “law-like” societal cultural rules and ideas that govern our behaviors and shape our perceptions of reality (King, 2005b). This system of knowledge and representation defines “conceptual blackness” as the “alter ego” of “conceptual whiteness” (Wynter, 2003). Although “whiteness” studies have begun to proliferate, this understanding of what “race” does and which grasps the epistemic roots of assaults on cultural blackness, is under-theorized in education (Bush, 2004; Ignatiev, 1995; Jensen, 2005; Kent, 1972; Prager, 1982; Roediger, 1998).

The blues epistemology of the Black experience

The task of fighting racism, then, entails the production of knowledge to combat this system of representation. It seems reasonable to expect that such research would benefit from the inclusion of epistemologies of marginalized peoples. Researchers of color recognize the intimate connection between epistemology and methodology when justice is the objective (Bernal, 1998; Pizarro, 1998). The African American blues tradition, discussed next, offers such an epistemological vantage point from which to document, interrogate, and transmit knowledge of the existential Black experience. This discussion is intended to illuminate four key characteristics of the blues epistemology that: (a) embraces the contradictions in the Black struggle for being; (b) functions as a unifying impetus for community building; and (c) provides clarifying social explanation, political knowledge, and spiritual understanding that is not solely for race consciousness but also (d) to connect Black suffering with the universal ideal of the human spirit of freedom. The following historical overview presents the rich, underutilized potential of this epistemology for teacher learning and research about and also through African American cultural perspectives.

Critical social explanation/theorizing

McLaren and Farahmandpur (2001) define theory as a “living aperture through which specific histories are made visible and intelligible” (p. 301, cf. Grande, 2004, p. 28). The blues tradition constitutes a form of critical Black working class theorizing or social explanation. Woods (1998) argues that the blues constitutes an epistemology of African American thought that embodies “African American daily life, social explanation, [and] social action,” that is, “how to act,” solve problems, and behave (p. 101). Blues lyrics, which typically address themes of love and mistreatment, have often been misinterpreted as a “music of resignation.” On the contrary, as Titon (1990) posits, the core of the blues is about “freedom from mistreatment, not submission to it” (p. 2). Whereas Black people have been subjected to unspeakable dehumanization, the blues response is love.

The record of African American cultural resilience and critical social thought conveyed in the blues contrasts with the culture of poverty deficit “theories” of Black life and culture that emerged in the social sciences in the U.S. around the same time that the blues moved along with Black people from rural areas of the Mississippi Delta to the urban north. Woods provides this illuminating account of the emergence of the blues tradition of “cultural transmission and social explanation”:

Emerging out of the rich tradition of African song-centered orature, and under conditions of intense censorship, secular and sacred songs became fountainheads of cultural transmission and social explanation. Furthermore, as a result of the extremely hierarchical class structure of Southern plantations, African-American working class thought would come to find its fullest expression in the blues: a “collective
expression of the ideology and character of Black people situated at the bottom of
the social order in America.”

Black Studies scholarship recognizes in the “historic commitment to social and personal
investigation, description and criticism present in the blues” a resource for critical know-
ledge and a source of theory (Woods, 1998, p. 30). In one program teacher educators
and future teachers have studied blues culture, history, lyrics, and the lives of blues
performers as aesthetics education (Asher et al., 2006; Love, 2006). Considering the
subjugated knowledge traditions of Black people (or any other marginalized cultural
group) as an epistemological resource for pedagogy, theory, or methodology in research,
however, requires a revolutionary break with the dominant societal episteme or system of
knowledge.

A people’s marginalized history

The blues emerged in the 1890s during the violent repression following the brief period of
“freedom” between the end of the Civil War and the end of Reconstruction. Political
“compromise” and betrayal resulted in the removal of Black troops and militia (“the
Black and Blues”) and the reinstatement of planter power and racial terror throughout the
south (Cone, 1972; Ortiz, 2005; Woods, 1998). It was during this period that the “hollers”
that became the central elements of the blues emerged, as the formerly enslaved were sav-
agely forced back to labor in unfreedom (again) on the levées, in the “fields, prisons, docks
and streets” (Woods, 1998, p. 82). Levine (1977), in Black Culture, Black Consciousness,
situates this blues tradition within the heritage of Black community building:

Black secular song, along with other forms of oral tradition allowed [Black people]
to express themselves communally and individually, to derive great aesthetic pleasure,
to perpetuate traditions, to keep values from eroding, and to begin to create new
expressive modes. Black secular song revealed a culture which kept large elements
of its own autonomous standards alive, which includes a rich internal life, which
interacted with a larger society that deeply affected it.

(p. 297, see Woods, pp. 56–57)

As the following passage explains, the blues represents a collective response to this
repression in the form of the “conscious codification of African American folk wisdom”
and knowledge out of which other musical forms also evolved:

The derivative of these forms such as jazz, gospel, rock and roll, rhythm and
blues, funk, and rap all refer back to these anchors and their insights. These new
musical genres are documentary in nature. That is, they must still explicitly, or
implicitly, address African American consciousness of this period and the intellectual/
performance traditions that emerged during it.

(p. 83)

As an indigenous “American” art form (native to this country), which remains deeply
rooted in an African ethos (values, functionality, and worldview) that survived among
African Americans, the blues constitutes a unique social vision and critique of injustice
that has been marginalized in, if not totally erased from, history. A wholly authentic
but often maligned and misinterpreted musical form through which Black people have
expressed a refusal to accept mistreatment, the blues can be understood philosophically as a “black point of view in song” (Davis, 1995, p. 69). The educational relevance of the blues is suggested in one artist’s understanding of the meaning of the blues:

To me, the blues is a literary and musical form and also a basic philosophy. When I get ready to study the mystical aspect of black people, I go to the blues, then I feel like I’m in touch with the root of black people.

(Palmer, 1982, pp. 276–277)

According to Woods (1998), this blues epistemology represents “the beginnings of a method of investigation” (p. 21) that can recover “heroic movements” of Black cultural resistance that have been purged from “both historical texts and popular memory” (p. 4, emphasis added). This critical knowledge tradition is a cultural constant in Black music, including the blues as well as some forms of rap music and “conscious” hip-hop (Fisher, 2003, 2006). In the aftermath of Hurricane Katrina, for example, hip-hop artist Kanye West’s criticism that President George Bush “doesn’t care about Black people” has been “sampled,” widely disseminated, and immortalized in a rap video/song via the Internet. In Blues People Jones (1963) explains that “the most expressive [Negro] music of any given period will be an exact reflection” of Black existence (p. 137). Following this line of reasoning, this chapter explores theoretical and methodological implications of this epistemology for group-affirming research in teacher education.

More than a musical genre

If language refers to a shared system of communication used by a nation, a people, or other distinct community, the blues “speaks” a communal language of the lived culture, material reality, and existential philosophy of Black existence. The blues gives voice to Black cultural ideals in a spoken record of Black suffering and transcendence that remains relevant and instructive. When visiting the Maori people in New Zealand, Bernice Johnson Reagon, African American historian, cultural activist, and founder of the incomparable female a cappella ensemble “Sweet Honey and the Rock,” offered this insightful observation about Black music that also applies to the blues. Taking part in a discussion of “the significance of land to Maori identity,” Reagon described the African American community “as one held together by song rather than by territory” (L. Smith, 1999, p. 126). Reagon’s research and performances have revealed the deeper meaning embodied in the language of the African American sacred song tradition. When Christianity was being used explicitly to justify Black people’s enslavement, for example, sacred songs—“Negro spirituals”—made use of Christian religious language and concepts with great critical insight and intelligence to repudiate this dominant ideology. A profoundly meaningful verse, “Everybody talkin’ bout heaven ain’t going there,” in one of these “sorrow songs,” All God’s Chillun Got Wings, illustrates the subversive “reading” of the “Word” and the world encoded in these songs. The injustice that Black people have suffered has also given blues singers and song writers opportunities to explore universal human themes made “specific through the African American experience” (Titon, 1990, p. 11).

The blues vision

The vision of social, cultural, interpersonal, economic, and racial justice in the blues implies certain conditions of freedom from mistreatment. As expressed, for example, in the blues song, “Further on up the road . . . someone is gonna hurt you like you hurt me,”
the blues conveys a universal philosophy of how people should be treated. The spirit of love in the blues honors humanity’s triumphal capacity to transcend dehumanization without diminishing or relinquishing the “space of being” in which Black people exist (Grande, 2004). Whether expressed in the determination to overcome heartbreak or hopelessness (“Been down so low, down don’t bother me . . .”), the refusal to accept mistreatment (by a lover, a sheriff, or a bossman) affirms the singer’s “somebodiness,” that is to say, Black people’s humanity (Cone, 1972). This vision of inclusion (in the human family) is neither “raceless” nor distorted by the mythology of race. Like the proverbial “crossroads” of the “deep blues,” where the most accomplished performance of the art that any artist aspires to achieve is possible, the blues vision of humanity suggests a powerfully transformative reason for knowing: to honor individuality, group heritage, and human freedom—all at the same time—in spite of the depredations heaped upon one for being Black and poor. This is the essence of the unique democratic contribution of the blues.

**The white blues**

A long-standing controversy in the music world about the “white blues” concerns whether, given the traditional themes and content of the lyrics, the blues as played by white performers is “authentic.” Some white performers argue that race should not matter in appreciating a virtuoso performance. Music critics and musicians remain at odds (Garon, 1995). This debate recalls persistent ruminations regarding “color-blindness” in teacher education literature. Within a guilt/innocence either/or mindset white pre-service teachers may profess to being and may prefer to remain “color-blind.” These teachers resist the goals of racial-social justice teaching by proclaiming racial innocence and a commitment to a notion of raceless equity, but with no vision of an end to racial oppression. For another example, in research and teaching contexts, critical theorizing that privileges social class and capitalist relations of production posit a class versus race theoretical explanation that, in effect, privileges “hybrid” conceptions of being and identity as opposed to Black identity and cultural integrity. Researchers or practitioners who embrace “color-blindness” call to mind the standpoint of “white blues” aficionados who “refuse to see race as a criterion for anything.” The “decolonizing” research methods of indigenous peoples, as discussed below, affirm transformative research possibilities that aim to ensure their cultural well-being, free from racial mistreatment, “annihilation and absorption into the democratic mainstream” (Grande, 2004, p. 172).

**Decolonizing methodology/indigenous epistemologies**

The importance of identity, cultural rights, community building, and belonging in the Black intellectual tradition is mirrored in methodological and epistemological alternatives to denigrating culture that indigenous education offers (Loveland, 2003). For example, “decolonizing” research methods and scholarship in Maori, Native Hawaiian, and Indian education and research practice prioritize community and student well-being in the context of a communal future, a sense of peoplehood, and indigenous people’s culturally sovereign “space of being” (Grande, 2004; Kana‘iaupuni, 2005; Kaomea, 2005; L. Smith, 1999; G. Smith, 2004). In these approaches educational purpose goes beyond the traditional value system promulgated in U.S. public schools that emphasizes competitive individualism and individual academic success, high stakes test scores, materialism, etc. These outcomes imply values that are deemed “alien” to the culture of achievement of indigenous peoples as well as African Americans (Murrell, 1997).
Proponents of the cultural rights of dispossessed and indigenous peoples in education use methods that are intended to illuminate “curricular silences” regarding the cultural and historical circumstances of indigenous communities and recover their collective heritages. Kaomea (2005) notes that such knowledge has been “buried, written over, or erased” and sometimes distorted beyond remembrance or recognition. One consequence has been the alienation of indigenous peoples from their own identity and heritage (Rollo, 2006). Native Americans and other indigenous educators, including the Maori of New Zealand, are using their heritages, languages, and other forms of “local knowledge” as pedagogical and methodological resources to: counter alienation, provide direction to research, preserve their culture, foster student achievement, and to ensure their collective survival as distinct peoples.

L. Smith describes Kaupapa Maori, or research by Maori people of New Zealand, for example, as more than a “paradigm.” That is to say, it is also a social project “related to being Maori” that is “connected to Maori philosophy and principles” and “takes for granted the validity and legitimacy of Maori.” The reason for knowing in Kaupapa Maori research also concerns Maori people’s struggle for autonomy and “cultural well being” (Smith, 1999, p. 185). Kaupapa Maori does not exclude non-Maori researchers but provides opportunities for their participation via equitable, authentic relationships with Maori partners. Along these same lines, as Angayuq Oscar Kawagley, Yupiak Elder and professor of education at the University of Alaska, Fairbanks, observes: “The tide has turned and the future of indigenous education is clearly shifting toward an emphasis on providing education in and through the culture, rather than about the culture. Critical to such indigenous approaches to education and research is language, which is “the living artifact of a culture” (Loveland, 2003).

Grande (2004), another indigenous scholar, clarifies the difference between indigenous people’s cultural well-being and the vision of social change/equity/democracy in progressive/revolutionary/critical theory and pedagogy. From the epistemological vantage point of “Red pedagogy,” according to Grande, regardless of the choices of particular individuals:

... what distinguishes the indigenous struggle for (group) self-determination from others is ... their collective effort to protect the rights of their peoples to live in accordance with traditional ... ancestral ways.

(p. 172)

Moreover, “this allegiance to traditional knowledge,” including the preservation and use of indigenous language that conveys the peoples’ “thought-world,” has protected American Indians from total “annihilation and absorption” into the homogenizing, “democratic” European-centered “mainstream.”6

Given that white teachers are the majority in the teaching force and given the various ways many white teachers (and parents) resist equity in education, it is not surprising that so much social justice-oriented teacher education research is directed toward understanding the “ideologies of privilege” of white teachers (Oakes et al., 2006, p. 95). These efforts typically focus on the needs of experienced and prospective white teachers (e.g. their resistance or cultural encapsulation). One alternative is to create authentic research partnerships and methods of inquiry as “communities of practice” in which the epistemologies of community people are made relevant in the assessment of these efforts (Murrell, 2001). The problematic belief structures of white teachers can also be addressed via theory, research methods, and pedagogy that illuminate the “ideologies of otherness” that are at the epistemic root of race-based inequities in schools and society. Before examining this
epistemic problematic using the conceptual tools of Black Studies, the trajectory of critical social theorizing from social science to educational approaches is discussed next.

FROM CRITICAL SOCIAL THEORIES/THEORIZING TO CRITICAL RESEARCH METHODS

In contrast to positivism, critical research approaches share a connection with the emancipatory aims of critical social theories (e.g. neo-Marxist, feminist, postcolonial). Qualitative educational research has common roots in the interpretive traditions in sociology and anthropology that bear the influence of various post-positive theory and methods, including phenomenology, structuralism, semiotics, hermeneutics, symbolic interactionism, and ethnomethodology (DeMarrais & LeCompte, 1999).

Critical roots in common

Carr and Kemmis (1989) made a relevant distinction between critical social theory and critical social science. Critical theory is the result of a process of critical analysis. Critical social science is a form of practice in which consciousness (the enlightened human agency of individual social actors) “comes to bear directly in their transformed social action” (p. 144). Critical educational theory has been criticized for a “tendency toward social critique” without theorizing action that practitioners can use to “develop a ‘counter-hegemonic’ practice” to challenge domination (Anderson, 1989, p. 257). Other scholars view critical educational research as a mode of inquiry to collect data about “schooling practices and their relationship to the social order” of power in order to “ultimately undermine and transform that order” (Morrell, 2005, p. 42).

Critical social science rejects the epistemology, ontology, and determinism of logical positivism. The goal of positive social science is to explain social life, while the alternative offered by interpretive social science is to facilitate understanding of domination and alienation. Following Marx, critical social science is informed by a moral obligation to understand social reality in order to change it. Thus, the dual aim of critical social science is simultaneously to explain and to combat dominating relations of power in favor of democracy and human freedom. The notion of “critical” applied to theory and methods of inquiry and in education (and teacher education) can also be traced to Marx’s understanding of the necessity of “ideology critique” for social change. Critical pedagogy (Giroux, 1988; Sleeter & Bernal, 2004), which is the analytical tool of critical theory applied to pedagogy, is indebted also to the Brazilian educator, Paulo Freire (1970/1993). Critical consciousness is a goal of Freire’s revolutionary pedagogy of liberation. In addition to these European, Euro-American, and Latin American roots of critical and qualitative research methods and theory, this chapter draws on the work or a number of scholars of color whose scholarship is influenced by the principles of critical social science. Table 54.1 (below) compares the common central features and distinct assumptions and concerns of critical social theory with feminist, critical multicultural, and race-central methods, theory, and pedagogy in social and education research.

Feminists, scholars of color and race-centered theorists criticize the lack of explicit attention to gender and women’s oppression, race, ethnicity, and cultural sovereignty of indigenous peoples in critical theory and critical pedagogy (Ellsworth, 1998; hooks, 1997; Ladson-Billings, 1997; Leonardo, 2004; Lynn, 1999). However, critical theorists strenuously reject the allegation that in giving primacy to social class, critical theorizing

- CST: Critical Social Theory
- CRT: Critical Race Theory
| Explanatory constructs | CST argues that domination is structural. That is, people's everyday lives are affected by larger social institutions such as politics, economics, culture, discourse, gender, and race. CST illuminates these structures in helping people understand the national and global roots of their oppression. | A critical feminist pedagogy intersects a postmodern feminism with critical praxis understood within the context of economic, political, and cultural constructs (Brady). A critical feminist methodology can illuminate the dual process of social and cultural reproduction and resistance—as in critical educational theory (Weiler, 1988, p. 59). | Race is a social construct, not biological. |
| Conceptions of consciousness | CST argues that structures of domination are reproduced through people's false consciousness, promoted by ideology (Marx), reification (Lukacs), hegemony (Gramsci), one-dimensional thinking (Marcuse), and the metaphysics of presence (Derrida) . . . CST pierces false consciousness by insisting on the power of agency, both personal and collective, to transform society. | Women should reject male supremacist thinking: to be female is to be a victim—and embrace their shared commonalities, the ability for self-determination, and communal agency (Brady) . . . Students should be offered the knowledge and the skills that allow them to reclaim their voice and their history . . . to enable them to name new identities . . . to assume ownership, and become active agents in their own lives (Brady, 2000). | Elites act against racist behavior in society only when it serves them, thus a critique of Liberalism's belief in steady but incremental processes of social change is an important component of CRT. |
| Key assumptions | CST argues social change begins . . . in people's every day lives—sexuality, family roles, workplace . . . | Feminist anti-racist teachers and administrators hold certain beliefs about justice and equality that they try to put into effect in their work to redefine the curriculum and social relationships (e.g. feminist counter-hegemony) (Weiler, 1988, p. 101). | Racist behavior is not an aberration, but is normal practice. |

fails to address forms of oppression other than that of social class (McLaren, 2000; Scatamburlo-D’Annibale & McLaren, 2004). These critical theorists assert that such “miscued” criticism incorrectly assumes the working class is white. Also, within a class-based (e.g. class-first) radical political economy framework the meanings of socially constructed categories of difference or subjectivities (e.g. gender, race and ethnicity) are produced by the class-based relations of production that define the capitalist system. Thus, these categories of lived experience and identity are interrogated and interpreted through the lens of the material (objective) relations of social class, power, and privilege linked to the relations of production (pp. 188–189).

Ongoing class versus race (or gender) debates illustrate the complexity of competing theories of social change. A radical Black Marxist tradition also exists that posits a class-first analysis. Multicultural and feminist approaches offer various interpretive frameworks to transcend this debate. Given that race is a social construction, scholars also posit that “hybridity” is a more useful conceptualization of being and identity than race (McCarthy, 1998). African-centered theorists and indigenous scholars, on the other hand, give primacy to peoplehood (Bernal, 1998; Grande, 2004; L. Smith, 1999). Identifying with one’s group heritage is considered neither an epiphenomenon of social class (or gender), a reactionary form of in-group solidarity, false consciousness born of societal exclusion (Hilliard, 2001; King, 2005b), self-deceptive “fictive” kinship, nor misguided, romanticized identification with “dead civilizations” on foreign continents (King, 2005b). In fact, recent research documents the power of “race-ethnic self-schema” to buffer students from the racial vulnerabilities of alienating schooling (Oyserman et al., 2003).

CRITICAL RACE THEORY AND METHODS

According to Lynn (1999), in asserting that critical pedagogy had “failed to adequately address the question of race,” Tate (1994) and Ladson-Billings (1997) helped put “race back into critical pedagogy” (p. 153) by applying the principles of critical race theory (CRT) in education. First articulated by legal scholars, then applied to education, critical race theory is an analytical lens developed by scholars of color to place race at the center of social analysis (Ladson-Billings & Tate, 1995; Parker & Stovall, 2004; Solórzano, 1997). Four precepts, delineated by Ladson-Billings (2005), define CRT in education. Critical race theory (CRT): (1) presumes that racism is normal not an aberration; (2) employs story telling as a mode analysis; (3) necessarily includes a critique of liberalism; and (4) points out that whites have been the primary beneficiaries of liberal/reform efforts (Ladson-Billings, 2006, pp. 300–302). In their introduction to a theme issue of *Qualitative Inquiry*, for example, Lynn et al. (2002) describe CRT as an “ontological and epistemological framework with which to analyze race” (p. 5). Sleeter and Bernal (2004) emphasize that CRT, in addition to addressing the “intersectionality of racism, classism, sexism, and other forms of oppression,” challenges Eurocentric epistemologies and dominant ideologies (e.g. meritocracy, objectivity, and neutrality) using “counterstorytelling as a methodological and pedagogical tool” (p. 245). Also, Pizzaro (1998) uses a CRT framework to develop research methods that are consistent with a Chicano/a epistemology.

A theme issue of *Race and Ethnicity* considers the impact of CRT in the ten years since the publication of Ladson-Billings and Tate’s seminal article on critical race theory in education and teacher education (Dixson & Rousseau, 2005). While CRT theorists criticize the idealized standpoint of “color-blindness” in the dominant discourse (Dixson & Rousseau, 2005; Ladson-Billings, 1997), other scholars who have studied race and
ethnicity in the social sciences argue for some degree of caution with respect to use of the construct race. The concern is not to argue for a class-first analysis but to emphasize that focusing on race as an analytical category can displace a needed critique of supremacist ideology and thereby reify a false, ideological construct (Hilliard, 2001; Stanfield & Dennis, 1993). However, critical race theorists argue back that CRT illuminates the “everyday-ness” of racism and values and represents the voices, strengths, and complexity of the experiences of people of color (Chapman, 2005, p. 28; Lynn, 1999). Proponents of CRT use methods such as narrative inquiry, counterstories, historical ethnographies, autobiography, autoethnography, critical ethnography, and portraiture in teacher education research. In the passage below Duncan (2005) describes links between the use of these methods used by critical race theorists and Freire’s liberation pedagogy:

The centrality of narrative and storytelling in critical race approaches to educational research is consonant with Paulo Freire’s (1995) view that changing language “is part of the process of changing the world” (pp. 67–68). Along these lines proponents of CRT in general emphasize aesthetic and emotional dimensions in their stories to stimulate the imagination and to inspire empathy to allow others to imagine the mind of the oppressed and to see, and perhaps vicariously experience, the world through their eyes.

Thus, these scholars argue that critical race theory has the capacity to convey to others “insider” knowledge of race as difference.

A CRT framework for qualitative inquiry

Critical race theory also provides a framework for qualitative inquiry in teacher education (Duncan, 2002; Ortiz & Rhoads, 2000; Parker et al., 1999; Sleeter & Bernal, 2004; Smith-Maddox & Solórzano, 2002; Solórzano, 1997). Emergent CRT “offshoots” include “critical race pedagogy” (Lynn, 1999) and “critical race ethnography” (Duncan, 2005). CRT has also generated a number of other complementary “connecting parts”: LatCrit (Latina/o critical race theory), Tribal Crits, FemCrits (critical race feminists), Asian American poststructural critical legal positions, and critical race feminism (Brayboy, 2005; Parker & Stovall, 2004; Sleeter & Bernal, 2004). Following are examples of how Black, Latina/o, as well as white teacher educator-researchers employ the CRT framework to study their professional practice. These researchers use “counterstories” and narratives to analyze their experiences teaching mostly white future teachers. For instance, Duncan (2002) describes pedagogical strategies he employed in an urban ethnography course that “rendered race visible.” That is, CRT has the power to bring “subtle forms of racial oppression . . . into bold relief” (p. 102). Other frameworks that are combined with CRT include Freire’s problem-posing method (Smith-Maddox & Solórzano, 2002), portraiture (Chapman, 2005), and Black feminism, which is discussed in the next section.

Black feminism and CRT in teacher education

In an article titled “The Burden of Teaching Teachers” Williams and Evans-Winters (2005), two African American women teacher educators, use the “lenses” of both Black feminism and CRT in reflective narratives of teaching white students. Reflecting on this experience they ask:
(1) [H]ow can those of us, who are on the side of social justice, bring race talk back into the public forum of the teacher education classroom and (2) how can we get the message to be digested, interpreted, and critically examined by teacher education students who benefit from systematic inequality?

The authors describe Black feminism/womanism as an ideology and political movement “that examines issues affecting African American women in the United States as part of the global struggle for women’s emancipation” (p. 204). Black feminism and CRT are presented as “the hope for teacher education.” Black feminism (BF), as an extension of critical social theory, is concerned with “fighting against economic, political, and social injustice for Black women and other oppressed groups” (pp. 203–204; also, Collins, 2000, p. 9). The authors use these frameworks in a complementary fashion to examine their professional practice.

Williams and Evans-Winters take a morally engaged, activist stance toward “the powers that be” (department chairs, academic deans, provosts) and concerns that arose when their mostly white female student teachers and their supervisors questioned, “interrogated and dismissed” their teaching practices. Their recommendations to improve the climate for Black women professors engaged in social justice-oriented teacher education include suggestions for: (1) an alternative method of evaluation that takes students’ retaliatory resistance into account; (2) mentoring to support the retention of faculty of color; and (3) holding open discussions about “learning from and with faculty of color” to address “who [which professors] students resist and why” (pp. 216–217). Challenging and changing institutional practice fulfills an important principle of critical race theory and is a central tenet of critical social science. As Dixson and Rousseau (2005) note:

It is not enough to simply tell the stories of people of colour. Rather the educational experiences revealed through these stories must be the subject of deeper analysis using the CRT lens. Furthermore, CRT mandates that social activism be a part of any CRT project. To that end the stories must move us to action and the qualitative and material improvement of the educational experiences of people of colour.

(p. 13)

The research examples discussed next illustrate critical ethnographic research methods in K-12 venues.

**Critical ethnographies: engaging Xicana teachers and urban youth**

According to Anderson (1989), the “overriding goal of critical ethnography,” unlike other interpretivist research in sociology and anthropology “is to free individuals from sources of domination and repression” (p. 249). Two examples of critical ethnographic research, which provide opportunities for empowering learning in high school contexts, illustrate very different conceptualizations of race in critical research for educational and social change. Xicana high school teachers and Black and Latino/a “urban” students who are trained as “apprentices” study their own experiences using a combination of critical ethnography and participatory research (Carspecken, 1996).
Xicana teachers as agents of change

Berta-Avila (2004) combines the methods of critical ethnography and participatory research to provide an environment for self-identified “Xicana” teachers to participate in an emancipatory “dialogic process.” This research experience illuminates connections between these teachers’ identity and their mode of critical (raza/race) pedagogy. Berta-Avila uses dialogues, journal entries, and observations to understand how these teachers perceive their role in the classroom when teaching Raza students. Language and (collective) self-identity emerged as important considerations in exploring these practitioners’ self-conceptualization of being “critical Xicana” teachers. They view how and why they teach as a “political act for social transformation and the emancipation of Raza students.” For instance, one teacher participant links her role as a teacher to her “Xicana” identity in a way that embraces her ethnicity, including her “indigenous roots”:

Xicana is how I identify myself culturally, historically, politically, and socially. I would expect a person who identifies him/herself as Xicana/Xicano to know her/his history and take pride in their indigenous roots. I would expect them to have a sense of responsibility to their community and be an advocate for those who have no voice and are silenced. I would expect them to understand what being political means...

(p. 70)

Berta-Avila concludes that “grounding themselves in pedagogy for social change” and engaging the issues of race, class, and gender enables these teachers to expand their role in the classroom. Beyond being a “role model,” who uncritically emulates a Euro-dominant consciousness and individual upwardly mobile success, these teachers see themselves as “change agents,” who “critically challenge and address power relations” that affect their students and their communities (p. 68). As another teacher explains:

If a Xicana/Xicano enters the classroom and has no social and/or political understanding of the institutions they are entrenched in, they then lack the skills needed to understand how educational systems and the dominant society are intertwined. He or she falls into the danger of perpetuating messages that Raza life experiences are not valid and they should forsake their identity in order to succeed in the United States.

Thus, Xicana/Xicano identity influences the relations between these teachers, their students, and the students’ parents, from whom they learn and for whom they choose to serve as advocates and cultural models. For these teachers, then, “it is not enough to be just a teacher of color.”

The descriptions of the “critical Xicana” practitioners in this study are consistent with other researchers’ reports of the political clarity of teachers of color (Beauboeuf-Lafontant, 1999; Irvine, 2003; King, 1991b; Ladson-Billings, 2000b; Lynn, 1999; Murrell, 1997, 2001). On the other hand, the research literature also describes Black and Latina/o educators (and researchers) who favor assimilation and who are highly critical of their own culture and language (Wills et al., 2004). Parents, too, who favor assimilationist goals, may adopt the dominant unfavorable view of their home language and culture.

Berta-Avila does not represent this study of Xicana teachers as an explicit investigation of or for teacher learning and development. However, the participatory research methodology employed afforded opportunities for these practitioners to reflect on their practice together and to examine the data and share their observations with each other. These
opportunities for reflection engaged the teachers and the researcher in intentional and unanticipated mutual learning. This study also indicates another important ability that scholars emphasize as essential for social justice outcomes for African American students and other marginalized students: developing students’ race-ethnic identities and identification with their communities and heritage are important resources for academic engagement (Oyserman et al., 2003). In the next example, however, high school students experience “becoming critical” without such a strong emphasis on race consciousness.

**Urban youth becoming critical researchers**

Morrell (2004), Morell and Collatos (2002), and Oakes et al. (2006) describe participatory social inquiry and organizing activities as learning opportunities that build communities of practice for pre-service and in-service teacher education, urban school reform, and community change using critical research methods. These collaborative research activities engage practitioners and community members as well as students in significant roles as co-researchers/change agents. For example, Morrell and Collatos (2002) trained a multi-racial team of urban high school “student sociologists” who participated in this program of:

... critical teacher education that forefronts authentic dialogue between pre-service teachers and urban teens ... who have been trained in the sociology of education [and who] provide mentoring to pre-service teachers enrolled in a teacher credential program.

(p. 61)

In this four-year project Black and Latino/a urban high school students studied social theory and completed “critical research projects related to equity and access to education” (p. 63). This critical ethnography of students’ literacy learning is situated within a postmodern cultural studies analysis of popular culture (e.g. neo-Marxian and Freire-influenced theories). Because racial “essentialism” is a concern, Black and Latino/a youth are described as “members of multiple cultures and communities” (Morrell, 2005, p. 5). Although Morrell affirms the existence of racial inequities and the utility of culturally relevant and multicultural pedagogy, this researcher argues against “conceptions of culture as mono-racial identity” (p. 39). In fact, a somewhat color-blind category, “popular culture” is one object of analysis. The question/dilemma Morrell poses for “critical educators who seek to educate for empowerment and access” is: “How do we effectively educate marginalized students in a way that addresses the impact of race yet transcends the social construction of race ... and unifies rather than divides?” (p. 15).

To summarize, research employing the framework of critical race theory and critical ethnography is contributing to a growing knowledge base on teacher education with critical social justice aims. We know less, however, about the design and effectiveness of teacher preparation experiences that contribute to the coherence of pedagogy, identity, and political understanding, particularly for teachers of color. This includes knowledge about how such learning experiences can intervene against internalized racism to “empower students of color to see the specific ways that whiteness causes them to think less of their individual and collective selves” (Allen, 2004, p. 128). A related problem is the support needed by faculty and “accomplished practitioners” who supervise and mentor these future teachers (Quiocho & Rios, 2000). Research is also needed that addresses how teachers and teacher educators can thrive in increasingly constraining and hostile educational contexts in schools and teacher preparation programs where technicist
rationality and assimilationist priorities predominate (Kincheloe, 2004; King, 2005b; Okpodoku, 2003; Scott, 2003; West-Olatunji, 2005; Wilson, 2005).

The change agent role the Xicana teachers in Berta-Avila’s study embrace suggests particular implications for teacher preparation. It would have been interesting to know something about how these Xicana teachers experienced their professional preparation. Did study of critical pedagogy, for example, inform their practice and shape their identity as Xicana teachers? Did Chicano Studies play any role in their professional development and identity? Morrell’s student co-researchers studied sociology of education texts. Would learning about racism through the lens of a Black Studies analysis of the blues epistemology, or studying Mexican corridos (ballads) that express Chicano values and history enhance the students’ abilities as mentors of pre-service teachers (Garcia, 2000; Pizzaro, 1998)? Can studying such forms of cultural expression illuminate important points of intersections in the social histories of people of color? In the research that concludes this section the focus is on how teachers can learn about racism. White women teacher educators use critical race theory in studies by white women professors who situate the pre-service and experienced teachers’ learning within the academic discourse of “Whiteness studies.”

Interrogating the discourse of whiteness

An emerging genre of critical qualitative research for teacher learning interrogates “whiteness” and ways that critical pedagogy and practitioner inquiry can contest unearned white privilege. This genre of “whiteness studies” includes critical and qualitative inquiry methods—journal writing, reflective dialogue—focused on “enlightening” participants regarding the educational implications of “white racial identity” and “white privilege.” The focus of these studies is the limited ways in which many white teachers understand issues of race and systemic racism, including their own racial identity and “privileged positionality” (Marx, 2004; McIntosh, 1993; McIntyre, 1997, 2002; Ortiz & Rhoads, 2000). This genre of research, which is an outgrowth of critical “Whiteness” studies in education, labor, and cultural studies, as well as critical race theory (CRT), interrogates the discourse of “whiteness” using practitioner and narrative inquiry. These studies can be situated along a continuum of focusing on teachers’ “cultural competency” (Irvine, 2003), critical multicultural education (Sleeter, 2001), critical feminist pedagogy (Brady & Kanpol, 2000; Weiler, 1988), and anti-racist pedagogy (Berlak & Moyenda, 2001; Kailin, 1994; Urrieta & Reidel, 2006; Zeichner, 1996). Typically the data in these studies is collected using qualitative methods (e.g. interviews, focus groups, student reflections/narratives) collected in single courses to document pedagogical impacts on future teachers’ self-identification and their understanding of societal or systemic (as contrasted with acts of interpersonal) racism. Data has also been gathered from multiple student cohorts, field placement experiences, and students’ collages, for instance. Two examples of this genre that describe three research contexts will be discussed in this section.

Becoming critical of whiteness

McIntyre (2002) has analyzed 95 collaborative collages created by 450 students in 19 (four undergraduate and 15 graduate) education courses. McIntyre’s students have constructed these collages and presented them in class to represent and explain their understanding of what whiteness means. In addition, two graduate courses also afforded the opportunity to engage students in critical readings and participatory community action research. One finding McIntyre reports is that many students came to “see whiteness as
an integral aspect of discourse” and they became aware of its impact on education. In another study Marx and Pennington (2003) employed a CRT framework to explore the racialized, culture-deficit thinking and identity issues that limited the ability of white teachers “to meet the needs of students of color.” These authors analyze their separate but complimentary exploratory efforts as self-described white teacher educators, who have “taken to heart the call of critical race theorists and critical Whiteness scholars to open up a White discourse on White racism” (p. 92).

Based on their understanding of the existing literature and their previous experiences teaching white student teachers, Marx and Pennington created “pedagogies of CRT that would draw the attention of white pre-service teachers to their own positionality and help them to become critical of it” (p. 92). These teacher educator-researchers indicate that they were cognizant of white (student teacher) resistance and resentments against “cultures of color.” They interpreted this resistance and resentment as markers of an (un)productive stage of white racial identity development that is “mired in White guilt, fear or anger.” (Such resistance, as discussed earlier in this chapter, continues to be a focus of the research of teacher educators of color, as well.) These experienced teacher educators engaged 12 white student teachers in two different settings in “supportive, trusting dialogical conversations” about the “taboo subjects” of race, “Whiteness,” and “White racism.”

Marx and Pennington describe the “sincere changes in attitudes” of student teacher/participants in these studies, their adoption of “new language,” their ability to see, name, and reject racism within themselves, and deficit thinking (about the children) “in everything from their teacher education classes, to the media, to their own home lives” (p. 105). Three student teachers participated in Pennington’s study. These future teachers apparently were stymied in their development by the realization that they “lacked the cultural knowledge to be effective in the classroom and to be effective in interacting with parents” (pp. 104–105). By contrast, Marx’s group of nine student teachers reportedly had empowering experiences by confronting racism in their teaching placements.

It deserves mention that the researchers in these three studies justify their pedagogical interventions on moral grounds rather than on the basis of demonstrated long- or short-term individual or institutional changes. The researchers do not report impacts on the actual practice of these future teachers nor are learning outcomes for the students they taught (and tutored) described. Despite student resistance, unsupportive university colleagues, and the warnings McIntyre received from a “disgruntled” administrator, she affirms her responsibility “as a white educator . . . to continue to provide prospective teachers” with opportunities to “see whiteness as a ‘center stage problem’ . . .” Marx and Pennington also articulate an explicit moral commitment to this “controversial work” on behalf of children of color:

Much of the work on Whiteness implies that the construct is too controversial, too risky, too complex to be used with undergraduates . . . We also see the effect on the children . . . Only when we are brave enough to undertake this kind of controversial work with our students and to fortify ourselves with the knowledge and skills we need to lead, will we be able to foster the necessary changes. Without this courage, our children of color will continue to be the ones left to absorb the truly destructive effects of White racism.

The committed stance of these teacher education practitioner-researchers mirrors the politically engaged practice of other scholars that will also be discussed in this chapter.
Unexamined/unintended implications: intersectionalities of race/gender/identity

One implication of researchers’ attempts to address white teachers’ “color-blind” thought through pedagogical interventions and practitioner inquiry is that the focus on “whiteness” may obscure other relevant identity considerations like gender (Gore, 1993). Much of the research on “whiteness” in teacher education is reported by white women teacher educators/researchers who are teaching mostly white female students. Cochran-Smith (2000) recounts her experience of becoming critically aware of her own “blind vision” regarding the continuing significance of race and racism in her teaching and research. Upon reflection, however she was able to gain the insight that white women teacher educators need to address the intersections of race and gender identity issues that are inherent in social justice teacher education. What Cochran-Smith recalls with regard to her own practice is worth noting:

“We,” I came to realize, often referred not to “we who are committed to teaching elementary school differently and improving the life chances of all children,” but to “we White people (especially we White women) who are trying to learn how to teach people who are different from us.”

(Cochran-Smith, 2000, p. 98, emphasis added)

In analyses of her teaching Cochran-Smith acknowledges that when the perspectives and experiences of the oppressed are not “sufficiently present” to inform the work, “blind-vision” can impair the efforts of white teacher educators to address issues of race, diversity, and social justice. She recalled, for example, discussions that had clearly focused attention on race in her work with future teachers. However, hindsight provided some understanding of what had escaped her vision and was missing in her approach:

It is clear to me now, though, that these discussions [in the teacher education program] were framed primarily for the benefit of White students who were invited to learn more about racism through stories of other people’s oppression.

(p. 92)

Two other research contexts are relevant in illuminating perspective blindness with respect to race/gender intersectionalities. First, in revisiting the data presented in their book, The Feminist Classroom, Maher and Tetrault (1997) acknowledge that they lacked the interpretive framework needed to “see” the ways that a (feminist) “pedagogy of positionality” must also excavate whiteness (p. 322). Using whiteness/race as a lens, their re-analysis reveals what had previously escaped their vision. Second, Berlak and Moyenda’s (2001) collaborative analysis of a classroom encounter with “whiteness” precipitated a reflective dialogue between the two women—a white Jewish radical teacher educator and a “militant” Black teacher. Their dialogue represents a unique examination of the intersectionality of race, identity, and gender in a teacher education context. Black and Latino/a teachers and teacher educators too often bear the “burden” of seeing what whites often do not see regarding the “taboo” work of dealing with race, often without adequate support from their white colleagues and administrators (Jervis, 1996; Williams & Evans-Winters, 2005).

This discussion of the intersectionality of race, gender, and identity suggests needed directions for research. For instance, do white women teachers and teacher educators experience racialized anxieties, “resentments” or “blind vision” in gendered ways that
differ from the experiences of white males? Do these dispositions affect their ability to work with families and communities of color? With boys and girls in their classrooms? Do Black women and Black men working with white women in teaching and research contexts experience particular antagonisms or vulnerabilities with regard to “whiteness” (or “blackness”) that are exacerbated by their differing historical experiences of race and gender? Finally, critical social theory defines ideology as “an organized belief system that represents social change as impossible, even if it suggests modes of individual betterment within the frame of reference of the existing social system” (Agger, 1998, p. 8). Sleeter and Bernal (2004) refer to ideology as “consciousness formation” of individuals, particularly their consciousness about how the society works” (p. 242). Do educators—no matter what their background—who are using a critical theoretical framework envision a collective future for children of color? Examples of practitioner inquiry in which the focus is on teachers learning to teach for social change in urban and culturally diverse communities are presented the next section of the chapter.

A CONTINUUM OF PRACTITIONER INQUIRY: LEARNING TO TEACH FOR SOCIAL CHANGE

The genre of practitioner inquiry usually refers to practice-based research conducted by practicing teachers. Also included is the study of practice for teacher education by teacher educators. The forms of practitioner inquiry discussed below include collaborative action research partnerships and guided community-mediated inquiry experiences to support pre-service and in-service teacher learning. These research approaches can be located along a continuum of practice-centered knowledge about teaching and teacher learning (in schools and teacher preparation programs) from individual self-study to collective action research to guided community-based inquiry in which learning from and with community members takes precedence.

Several major analyses of the various types of practitioner inquiry are available (Anderson et al., 1994; Cochran-Smith & Lytle, 2004; Zeichner & Noffke, 2001). Practitioner inquiry, that is, “systematic, intentional inquiry by teachers” (Lytle & Cochran-Smith, 1999, p. 84), is the term Cochran-Smith and Lytle (2004) use as a “conceptual and linguistic umbrella” to cover a number of research genres and modes of inquiry in which teachers engage in practice-centered investigation. Their extensive review of the literature demonstrates multiple and varying descriptions of forms of practitioner inquiry. Included are genres of research focused on teacher knowledge about teaching, pre-service teachers’ experiences while learning to teach (Britzman, 1991), collaborative investigations with practitioners and teacher educators, as well as the practice of teacher educators as the focus of inquiry. Rosiek and Atkinson (2005) identify three practitioner inquiry approaches related to understanding teacher knowledge and the process of learning to teach: (1) narrative inquiry/analysis, (2) action research, and (3) teacher research. These categories of practitioner inquiry are discussed below.

Narrative inquiry

Narrative inquiry, also referred to as self-narrative inquiry (Garcia, 1997), is multifaceted and includes various methods of practitioner inquiry, such as teacher reflective writing (in journals and diaries, for instance) and autobiographical writing. Autoethnography can also be included in this genre (Olsen, 2000). Forms of narrative inquiry such as teachers’ stories and life narratives reveal aspects of teacher knowledge and the experience
of learning to teach in different contexts (Clandinin & Connelley, 1990, 2000). For example, these methods have been used to explore the experiences of teacher support groups for novice teachers (Stanislaus et al., 2002) and the learning trajectories of pre-service teachers in “inner-city” teaching situations (Kea & Bacon, 1999; Rushton, 2001). Narrative inquiry reveals rich details of practical teacher knowledge and beliefs about teaching and learning. Like other forms of practitioner inquiry, studies of teacher learning using narrative forms seek their validation in the ways that “inquiry transforms practice” (Rosiek & Atkinson, 2005, p. 425; see also Feldman, 2003).

As the following journal reflection demonstrates, however, practitioner inquiry studies may show no evidence of teacher learning to transform their practice from the point of view of the lived experiences and epistemologies of diverse “others.” Consider the lack of insight, empathy, and critical understanding in this journal entry, for example:

What do you do with children who will not do their work, and every time somebody even brushed them they “explode in anger” but yet you know that their daddy is a drug dealer and they probably only get two hours of sleep a night?

(Rushton, 2004, p. 74)

This study reports this student teacher’s “unfavorable” classroom journey in an inner-city school resulted in a decision not to pursue a teaching career. Several studies by Cochran-Smith (1995; 1991), which have been collected in the volume Walking the Road: Race Diversity and Social Justice in Teacher Education, represent powerful examples of learning to teach for social change (Cochran-Smith, 2004) in ways that address such deficit thinking. In this body of work Cochran-Smith draws on teacher narratives to document the experiences of teachers learning to “teach against the grain.” The narrative accounts of these future teachers demonstrate how they come to see themselves as “both educators and activists.” Cochran-Smith provides a coherent theoretical rationale for this pedagogical approach.

Practitioner (narrative) inquiry research that documents the “voice” of pre-service teachers working in inner city schools, in particular, which has frequently involved single case-studies, is limited with respect to developing broader theoretical understandings (or generalizations) across contexts and situations (Rushton, 2004). Although forms of practitioner research have gained considerable ascendancy, this genre of research remains engaged for the most part with a “narrow range” of theory (Noffke, 1999). Indeed, largely missing from pre-service practitioner inquiry studies are forms of teacher knowledge and practice-centered theory generated from within the cultural realities and epistemologies of students of color, their families, and communities. Cochran-Smith’s (2004) research documents teacher learning in this direction. She suggests that teacher educators-researchers may also need to rethink what and how they teach in this regard and notes that “theories of practice developed by and about persons of color, as well as rich and detailed analyses of successful teachers of children of color, particularly poor children of color . . .” were missing from her work (p. 97, originally published in 2000). Alternatively, Ball’s study of the knowledge teachers need to effectively teach writing to African American vernacular English speakers recognizes the need not only for high expectations in the dominant society’s terms “but also standards of the students’ subcultures” (Ball, 1999, p. 243). Finding ways to draw upon and incorporate the perspectives and lived experience of community members in teacher learning and practitioner research in community contexts is an important dimension of the example of action research that is discussed next.
Action research as community-mediated inquiry

Action research, which can take many forms, has provided opportunities for both experienced teachers and future teachers to gain access to and to learn from community knowledge and perspectives (Gore & Zeichner, 1991). Noffke, one of the leading practitioners of action research in the field of teacher education, describes action research as “political, theorized practice” (Noffke, 1995, p. 3). This method of practitioner inquiry consists of a cyclical process of planning, acting, observing, and reflecting. Noffke and Somekh (2005) identify three types of action research: (1) the professional action research (focused on “improving services in a professional setting”), (2) the personal (focused on attaining “greater self-knowledge” and “a deeper understanding of one’s own practice”), and (3) the political (focused on “social action to combat oppression”).

The example of action research that will be discussed here is Hyland and Noffke’s (2005) long-term collaborative teacher education action research program. These teacher educator-researchers have studied their own practice with white pre-service teachers by combining teaching with two levels of practitioner inquiry focused on: (a) their own practice and (b) the learning-to-teach for change experiences of their pre-service students. Hyland and Noffke state that their aim was to deepen their understanding of “how community-based pre-service work may be used to develop a critical multicultural approach to the teaching of social studies” (p. 370). In collaborative inquiries in their social studies methods courses, taught in their respective teacher education programs at two different institutions, Hyland and Noffke use examples of the students’ learning as well as focus group discussions, journal writing responses to assigned critical readings, and community inquiry experiences as data. These teacher educator-researchers use these multiple data sources to ask about the impact of “critical study of injustice in history, politics, economics, and geography” (p. 371). They ask, for example, “In what ways do community inquiry assignments influence pre-service teachers’ understanding of marginality?” And “how do students see themselves in relation to the communities they investigate?”

According to Hyland and Noffke, teachers “need to understand and interrogate oppression in order to act against it in their classrooms.” Their action research program also demonstrates their belief that “teachers need to become allied with marginalized communities in the fight for social justice” (p. 379). For instance, they asked students at one of their institutions to develop a relationship with a community member and to collaborate on a lesson that used the perspective, life history, knowledge, talents or interests of the community member in that lesson. By using learning-to-teach experiences that involve community-mediated practitioner inquiry, Hyland and Noffke consciously model for their students some of the ways that curriculum and teaching can address social justice goals. These researchers report new understandings of ways to incorporate inquiry methods into their own teaching.10

Developing pre-service teachers’ self-understanding (and self-efficacy) in relation to teaching students from “historically marginalized” groups is one goal of the community-mediated inquiry activities Hyland and Noffke studied through collaborative action research. They note the fundamental importance of gaining “historical perspective” about the group being investigated for “making sense” of these inquiry experiences. The assigned critical readings provide “authentic perspectives of the group being studied” and are “essential to the inquiry experience” (p. 378).11 Some level of prejudice reduction among the student teachers is one result of these inquiry experiences that is documented in students’ oral and written narratives, collaborative reflections, and seminar discussions. However, these researchers also call attention to an important drawback in their
approach. In their efforts as critical educators who are conscious of gender issues from a feminist perspective, Hyland and Noffke attempt to resolve the contradiction of power and authority in their classrooms by giving their pre-service students the freedom to choose (comfortable) “cultural boundaries” to “cross.” They acknowledge that students sometimes choose the least “challenging” cross-cultural community inquiry experiences.

In addition, Hyland and Noffke report that community learning experiences can re-inscribe various forms of privileged positionality related to the student teachers’ race, gender, and class identity. In fact, pre-service students’ fear of going into urban neighborhoods is a recurring theme in the literature (Buck & Sylvester, 2005; Duncan, 2002; Swartz, 2003). Moreover, practitioner inquiry focused on teachers learning to center students of color in their own cultural identities and heritages, as well as the needs of their communities, is still largely missing from this genre of research (Goodwin & Swartz, 2004). Practitioner inquiry also tends to neglect teachers’ cultural and historical knowledge, that is, the mis-education of teachers that contributes to the problems of “whiteness” and dysconsciousness (King, 1991a). A number of teacher educator-researchers with considerable experience using anti-racism approaches in their courses speculate that college-level teacher preparation may actually be too late to change the deficit thinking and dysconsciousness of some future teachers (Berlak & Moyenda, 2001; McIntyre, 2002; Swartz, 2003). As will be discussed below, in contrast to course-based learning, teacher inquiry in the context of ethnographic study groups, learning communities, and communities of practice seem to provide support for more critical learning.

Ethnographic methods, practitioner inquiry and communities of color

Ethnographic research that engages experienced practitioners as co-researchers (Allen & Labbo, 2001; Bernal, 2002; Moll & Gonzáles, 2004) has generated forms of practical knowledge for teaching that build upon the “funds of knowledge” in the households of marginalized students (Gonzáles et al., 2005). This research recognizes that successful teachers of low-income students and students of color respect, have knowledge of, and establish relationships with students’ home communities (Irvine, 2003; Ladson-Billings, 1994; Moll et al., 1995; Zeichner & Melnick, 1996). As Moll (2005) has noted:

Teacher education is . . . a matter of developing not only technical competence and solid knowledge of subject matter but also sociocultural competence in working with the diversity of student that characterize contemporary schooling. (p. 244)

Torres-Guzmán, Mercado, Quintero, and Viera (with Moll, 1994) are among a new breed of researchers of color who have designed new roles for students, parents, and teachers to participate in collaborative ethnographic research. Their research project in New York City and Puerto Rico, and supported both teacher and student learning in and about Puerto Rican communities in new ways. Moll and Gonzáles have led this program of collaborative ethnographic practitioner research for more than two decades in Arizona and other locales. Practitioner inquiry experiences are combined with ethnographic home visits in order to identify social and cultural practices that can inform classroom instruction. Researchers and their practitioner co-researchers report that these forms of collaborative inquiry deepen teachers’ understanding of structural inequities by positioning them to “view urban communities as reservoirs of strength, possibility, and talent”
This is an important dimension of the way the cultural “funds of knowledge” research program makes the intellectual, social, and cultural assets in families “pedagogically viable.”

In summary, the growing acceptance of teacher education research produced in collaboration with practitioners represents a “hard-won paradigm shift” in the field (Cochran-Smith & Lytle, 2004). Significant strides have been made in giving “voice” to teachers as researchers of their own practice, including accomplished teachers and teacher educators of color. In addition, with varying results practitioner inquiry mediated by community knowledge takes many forms using various methods. For example, Allan and Labbo (2001) as well as Hyland and Noffke (2005) report that action research in urban communities has positively impacted prospective teachers’ learning when they use what they learned from self-reflective, community inquiries to develop lessons. Relatively brief excursions and more extensive immersion experiences include both observation and inquiry activities designed to “shake up” students’ deficit views in order to foster more critical awareness and understanding (Bernal, 2002; Duncan, 2002; Garcia, 1997; Wiest, 1998). Hyland and Noffke (2005) stress an important dimension of the need for such approaches in teacher education: “Unless our White, heterosexual students learn to understand diversity in new ways, the children from these [underserved] groups in their classrooms will continue to have to live within the dominant culture everyday of their schooling” (p. 378). Assets or strengths-based approaches are gaining coherence in a growing body of research and scholarship that demonstrates the value of community-mediated inquiry experiences for teacher learning (Boyle-Baise & Sleeter, 2000; Oakes, Rogers & Lipton, 2006). Less systematically developed, however, are modes of inquiry in which full-fledged reciprocal research partnerships incorporate community knowledge and perspectives in the purposes and conduct of collaborative inquiry. A vision of critical and qualitative research in teacher education for the cultural survival of marginalized students and their communities, as well as for teacher learning, is taken up next in the last part of the chapter.

BEYOND THE CRISIS OF KNOWLEDGE IN TEACHER EDUCATION RESEARCH AND PRACTICE

Teacher education research is only beginning to address the complexities that developing theory and practice in authentic democratic partnerships among researchers, teachers, and urban/indigenous community members entails. Noffke’s (1999) observation nearly a decade ago is worth repeating: “Theory generated within the work and lives of people of colour has only marginally been addressed” in teacher education research (p. 27). Murrell’s (2001) has made a similar observation that remains pertinent: the failure of educators “to draw on the local knowledge, perspectives, and cultural frameworks of people of color in diverse urban communities” is nothing less than a crisis of knowledge in urban education (p. 20). As Zeichner and Noffke (2001) point out, teacher education research is inherently connected to conceptualizations of teachers’ work and also to “debates about the overall goals of education in society” (p. 298). Preparing teachers who have the knowledge, competence, and the will to meet the needs of underserved students of color in K-12 classrooms and who can center their students’ learning in the epistemological perspectives of their families and communities remains beyond the purview of the high-stakes standardized testing regime’s “conservative agenda to produce ‘highly qualified teachers’ ” (Banks, 2004, p. ix; Malveaux, 2005).
Valuing/using community knowledge: a task for liberatory research

The “community nomination” method that Ladson-Billings (1994), following Foster (1993), employed to identify successful teachers of African American students illustrates how researchers can honor community knowledge, goals, and perspectives on education. Ladson-Billings relied upon the knowledge of community members to identify the criteria she used to select the teachers in her study of culturally relevant pedagogy. These criteria imply educational goals and pedagogy that transcend “conventional notions of the students getting good grades, scoring well on standardized tests, graduating from high school, going on to college, and securing good jobs . . .” (Ladson-Billings, 1994, p. 147). The parents Ladson-Billings interviewed “expressed an interest in an education that would help their children maintain a positive identification with their own culture.” As one parent stated: “I just want [my child] to hold his own in the classroom without forgetting his own in the community” (p. 147).

This parent’s goal, which expresses the communal ideal and social vision of the epistemology of African American achievement, can be understood as a “requirement for black existence.” Whether in the classroom or a blues performance, the traditional African American cultural ideal values individual accomplishment in the context of community well-being. This ideal contradicts prevailing conceptions of educational purpose and quality (Heath, 1982; Murrell, 1997). Boggs’s (1974) classic description of Black “education to govern” for the benefit of a transformed, more just, democratic society is consistent with Tedla’s (1997) articulation of “community mindfulness” as a goal of Black education and socialization. Following are examples of teacher education practice that value and use community knowledge in various ways and which suggest research questions and modes of inquiry for cultural well-being that are missing in “mainstream” teacher education research and practice.

First, in the “Community Teacher” model for effective urban teaching that Murrell (2002) has developed teachers, parents, school leaders, and community members participate as full-fledged partners in ongoing, collaborative practice-based community-mediated inquiry that supports teachers’ and African American students’ learning. Second, Hyland and Meacham (2004) propose a Community Knowledge Centered model of transformative teacher education that is centered on the “important and vital knowledge” that community members possess and that educators can learn with and from them (p. 123). “Community Scholars,” a project of New Ways to Learn, is a third model for teacher learning with and from community members. In this project (summarized in Figure 54.1) “low-income” public housing residents: (1) teach the teachers and teacher candidates how to respect low-income family members in schools and (2) decide to become schoolteachers themselves. Ishibashi describes this program:

Between 2002-present several classes of established teachers, teacher candidates, and aspiring teachers in classes at San Francisco State University and the City College of San Francisco have experienced learning with and from Community Scholars. In collaboration with tenant associations in publicly subsidized housing, educational organizations, public schools, service learning and mentoring programs, partnerships have created collaborative spaces where “low-income” community members teach the teachers how to respect them, their children, and extended family/community members, and they decide to become formal (credentialed) teachers themselves.

(Jean Ishibashi, 2006, Personal communication)
What distinguishes these three teacher education program approaches just discussed from the research in previous sections of this chapter? With the possible exception of the "funds of knowledge" ethnographic research collaboratives, each incorporates "authentic cultural knowledge of students’ home communities" (Hyland & Meacham, 2004, p. 114) through sustained, reciprocal engagement with community participants’ knowledge and ways of being. To the extent that community knowledge is salient as both content and process, these model approaches demonstrate important tenets of teacher education practice for cultural well-being. As such, these teacher education approaches represent emergent venues for cultural well-being research informed by the blues epistemology of the Black experience. Research within a cultural well-being framework from this epistemological perspective: benefits both teachers and the community; connects teaching and teacher education with the “Black struggle for being”; creates social inquiry spaces for (teachers and communities to be engaged in) the mutual investigation of the epistemic roots of the ideology of race (e.g. assaults on cultural blackness); and community building and social action in alliance with other groups are thus grounded in group-affirming heritage knowledge. Finally, these social inquiry spaces will provide opportunities for critical social and political investigation of community needs, for
spiritual ways of knowing and healing for Black consciousness and to identify with humanity’s struggle for freedom.

The crux of the matter is whose social vision prevails in racial-social justice-oriented research and how can this research be a liberating resource for social change? That is, what is the role of culture, heritage, and identity in research to combat the system of knowledge that propels racism and other forms of oppression? This question must be asked of various collaborative research-for-change efforts that engage students, teachers, and families as “critical” co-researchers (Cahill, 2004; Hammond, 2001; Morrell, 2004). My own research, which has not been identified in earlier publications using the terms “cultural well-being,” has created “research-as-pedagogy” contexts that have engaged educators, parents, and researchers in reciprocal inquiry activities that have helped to illuminate the “requirements of black existence” understood as a condition of the general welfare (King, 1991b, 1992, 2005a, 2006; King & Mitchell, 1995). An important consideration in this body of work, as noted below, is to devise research methods that afford opportunities for critical investigation of community needs and cultural practice as well as teachers’ knowledge and pedagogy:

This methodology recognizes that particular knowledge of the world contained in people’s daily cultural practice and social experience is not merely distorted by the dominant ideology. Rather, knowledge generated from and grounded in people’s culture and experience can be liberating as well.

(King & Mitchell, 1995, p. 67)

Black Studies and Ethnic Studies programs, an under-utilized resource for teacher learning and research, can provide opportunities for future teachers to gain access to community knowledge traditions and to interrogate the limitations of dominant knowledge. For example, Kiang (2004) describes a range of programmatic strategies using Asian American studies in a K-12/university partnership program that engaged Asian American prospective teachers in the recovery and affirmation of their cultural heritage. This program also provided African American and other teachers of color with valuable lessons about cultural diversity. Kiang concludes that ethnic studies programs can lead to and sustain powerful interventions in these areas precisely because of their foundational commitments to educational equity and social justice and their holistic relationships to diverse students, families, and communities.

Oakes et al. (2006) developed and describe various university-supported social “design experiments” that involve collaborative public inquiry and organizing for school and community change. This “learning power” program includes numerous examples of teachers, teacher educators, researchers, parents, and students engaged in sustained, “empowering” inquiry-based learning and “teaching for change” using critical and qualitative methods of research. (Morrell’s (2004) critical ethnography is a previously discussed example.) These scholars cite the democratic grassroots organizing of civil rights movement leader/teacher Ella Baker as a model for this “learning power” approach. However, Baker’s democratic social change methodology included coalition building from a “strong autonomous” African American community base (Ransby, 2003, p. 100). In Baker’s practice this meant developing people’s knowledge of and appreciation of their own history, culture, and identity—in the worker education curricula and in the Freedom Schools that she inspired, for example. As Woodson understood, such knowledge, from the ideological position of democracy, can facilitate multi-racial alliances but is also required to support the “space of being” marginalized groups need in a democratic society.
Teacher education research documents white teachers’ resistance to investigating their “emotional investment in particular beliefs, assumptions, and worldviews” (Urrieta & Reidel, 2006, p. 282) and their resistance adversely affects teacher educators of color and others who are committed to equitable education (Scott, 2003). However, framing teacher education research within the limited terms of a demographic imperative impelled by the predominate number of white teachers is an epistemologically inadequate “logic of inquiry” (Stanfield & Dennis, 1993). Such a rationale risks remaining circumscribed within the limits of white teachers’ mis-education and dysconsciousness (King, 2005b). Teachers need knowledge and skills that will enable them to teach in ways that foster students’ intellectual and social development without diminishing the cultural identities, languages, and heritages of people of color. Educational and research purposes need to be broadened to include community perspectives. However, community participants involved in teacher learning also need opportunities to develop a critical understanding of their lived realities, cultural practice, and social histories. Researchers need methods of inquiry that can capture the beneficial effects of such knowledge and that provide support for community members’ roles in contributing to and assessing the social utility of teachers’ knowledge and pedagogical skills in the context of community change and survival needs (Patillo-McCoy, 1999). Knowledge of the societal episteme is required for all. The opportunity to use this liberating knowledge in inquiry-based partnerships for professional teacher preparation is akin to the mutuality between the audience and the blues performer. Such new forms of knowledge and accountability in collaborative teacher education research and practice within a cultural well-being framework have implications for “the very notion of knowledge and how our definitions of what counts as knowledge produce hierarchies of power that have both real and symbolic effects on people’s lives” (Hyland & Meacham, 2004, p. 177).

CONCLUSION

Through the lens of a Black Studies analysis of the ideology of race, this chapter examines selected examples of critical and qualitative research in teacher education with racial-social justice aims. A focus on the value of community knowledge and marginalized epistemologies informs the discussion of four interrelated genres of critical and qualitative research “in, on, and for” teacher education. The chapter considers how and how well critical and qualitative methods of teacher education research value and use the social vision and epistemological perspectives of people of color. Also considered are models for collaborative research and practice that engage teachers and parents and community members in mutual learning.

The relevance of the blues epistemology for teacher education research is the authentic knowledge for cultural well-being this worldview perspective offers. The blues has been described as “a dispossessed people’s alternative to suffering and silence” (Davis, 1995, p. 84). What is missing in critical and qualitative teacher education research and practice? Effective ways to use the “subjugated knowledge” of the dispossessed as a liberating educational tool for cultural well-being and human freedom are lacking (Hyland & Meacham, 2004, p. 123). Also needed are spaces for social inquiry in which teachers, researchers, and community members can seek understanding in order to challenge the epistemic foundations of ideological racism in knowledge, research, and pedagogy. Historical understanding is crucial to address this crisis of knowledge in teacher education. At a time when “many people have lost hope in the possibility of liberal reform” in the U.S. (Bush, 2004, p. 11), West observes that it is time for a “blues nation to learn
from a blues people”—Black Americans. Yet, Black people’s cultural survival has never been in greater jeopardy. Duncan (2002) remarks that it is “fashionable nowadays to downplay and even dismiss race as a fact shaping the quality of life in the United States . . . in favor [of] class-based and gender-based approaches to understanding social oppression” (p. 93). It is even more fashionable to eschew anything that has to do with humanity’s debt to Africa and the African heritage of African American people (Robinson, 2000).

Critical educators, as well as liberals and conservatives share a concern about whether racial/ethnic cultural identification “unifies” rather than “divides.” Allen (2004) suggests a role for the subjugated knowledge of the oppressed in bringing about unity but within a transformed society:

. . . people of color must provide the major source of knowledge, inspiration, and sacrifice in humanity’s collective liberation from white racism . . . As people of color around the world engage in the struggle against global white supremacy, they should work to humanize both themselves and whites, when strategic. They should avoid the pull to follow the white model of humanity and instead replace repression with radical love . . .

(p. 134, emphasis added)

This is the universal message the blues epistemology conveys regarding another possible way of “being in the world” (Reagon, 2001)—a way of being that is an urgently needed alternative to the “western bourgeois model” of the human (Wynter, 2006). This model falsely defines being human in terms of the anachronistic construct of race.

The spectacle of a white man, a prominent community leader, weeping openly on national television because rescuers had failed to arrive in New Orleans after hurricane Katrina to save not only Black lives but white people as well, suggests a vital lesson the blues has affirmed for quite a long time:

If we are ever going to be a civilized [nation], we are going to have to begin to work as hard for the weakest and most maligned among us as we do for the strongest and most sympathetic. If we don’t, any of us could one day face the consequences.

(Sothern, 2005, p. 22)

Methods for transformative engagement with the Black experience, including study of the overcoming human spirit and conditions that continue to give rise to the hopeful determination of the blues, expressed in the most maligned of American languages (African American Home Language), offer a possible way out of the “utter terribleness of our new millennium” (Baker, 2001, p. 10). A “blues epistemology” for critical and qualitative teacher education research acknowledges Black people’s humanity, articulates cultural well-being as a reason for knowing, and allays a white discourse of guilt/innocence. We are all implicated.

Coda

It’s all my fault / I musta / Did somebody wrong . . .
Everything that’s happened / You know I am to blame.
I’m gonna find me a doctor / Maybe my luck will change.
My mother told me these days / Would surely come.
I wouldn’t listen to her / Said I gotta have some fun.
I musta / Did somebody wrong . . .

Elmore James, Blues Artist Extraordinaire

4 This student-teacher shared this information in class, with an apology, after she and other students had vehemently complained that this “cross-cultural communication” course was a “waste of time”. See King & Ladson-Billings, 1990.
5 This song is also titled, “Going to Shout All Over God’s Heaven.” See http://www.negrospirituals.com, retrieved November 1, 2006.
6 I use American Indian and Native American to refer to the indigenous peoples of the Americas, including the United States.
7 The “X” in the Xicana/Xicano movement, which replaces the “Ch” in Chicana/o, symbolizes the “all encompassing” political and spiritual struggle connecting different indigenous peoples throughout North, Central and South America, some of whom identify ancestral connections with the ancient Aztecs. A Xicana/Xicano movement “without borders” has evolved out of the Mexican American (Chicana/o) movement in the U.S. Southwest. “Raza” means race in Spanish. See Berta-Avila (2004), Note 1.
8 On the other hand, Elam and Jackson (2005) in Black Cultural Traffic examine “mass popular culture” using the category of “black popular culture” without denying aspects of its dynamic “hybridity.”
10 Buck and Sylvester (2005) report a similar approach using “community liaisons” to mediate pre-service students’ “entry” into urban communities. These community members facilitate pre-service students’ community ethnographies focused on identifying “funds of knowledge” or community assets.
12 The Board of Directors are: Jacqueline Elaine Featherston (formerly Elena Featherston), Alexandra Featherston Gomez, Virginia R. Harris, Jean Ishibashi, Margo Okazawa-Rey, Gwen Orto, Sylvia Ramirez, Noemi Sohn, and Diana Vielmann. This group of women of color, including low-income women, named the organization: New Ways To Learn. The project name, “Community Scholars,” was suggested by the late Dr. Beverly Robinson, of UCLA, an oral historian from the San Francisco Bay Area. (J. Ishibashi, personal communication).

Artifacts
8.1 Applying what we know
The field of teacher education

Nathaniel L. Gage

In considering how a scientific basis for the art of teaching can be applied, we obviously become concerned with teacher education. It is in that field that the application takes place—in preservice teacher education, where prospective teachers are prepared, and in inservice teacher education, where teachers already on the job improve their ability to do the job.

The importance of teacher education is commensurate with the importance of teaching itself. We do not want our children to be influenced by persons to whom we have failed to give the best possible preparation for their task. Nor do we want our enormous investment in teaching to yield anything but the best possible returns for our society.

THE STATE OF TEACHER EDUCATION

As everyone knows, teacher education has a long history of low status. It is possible to find statements concerning its poor condition in the nineteenth century and all through the twentieth. In our own time, that undesirable state of affairs has been set forth in volumes by James Bryant Conant (1963) and James Koerner (1963), and in Teacher Education, a yearbook of the National Society for the Study of Education edited by Kevin Ryan (1975).

Many of the criticisms of teacher education deal with its governance and only incidentally with its content. The debates on content are concerned with relative emphasis on liberal education and subject matter competence as against more strictly “education” courses, such as those in curriculum and teaching methods. The problem of content is seen in turn to be involved with governance—the distribution of power over teacher education. Liberal arts faculties, education faculties, organizations of teachers and administrators, and state education departments engage in struggles for this power. Such struggles were expressed in the 1950s in the writings of Arthur Bestor and Harold Hand.

Yet in a recent series of articles (Messerli, 1977; Wallace, 1977; LoPresti, 1977; Spencer & Boyd, 1977; King, Hayes, & Newman, 1977) it was repeatedly recognized that the power struggle is not more important than the research struggle for knowledge about teaching. Who determines what teachers should learn does not matter so much as what kinds of knowledge and what skills in teaching have been identified as worth learning. In short, although no armistice between the warring camps should be expected, the competition for control of teacher education should take second place to our concern with establishing a scientific basis for the art of teaching.

Thus, the poor state of teacher education is attributable, in part at least, to an insufficiency of the kind of scientific basis I have tried to sketch. This kind of explanation can be seen in the history of medical education. That field was diagnosed by Abraham Flexner (1910), in his epochal Medical Education in the United States, as extremely sick. He was able to bring about a cure, however, because even in his time medicine was “part and parcel of modern science.” The
scientific basis for the art of medical practice was imperfect in 1910—even more so, of course, than it is today. In Flexner’s words, medical science dealt “not only with certainties but also with probabilities, surmises, theories.” Yet, because medicine had a scientific basis, the weakness of medical education in 1910 could be contrasted with the strength of the scientific knowledge that medical research had built. We all know that the Flexner Report was able to raise medical education to a wholly new level because of the strength of that profession’s scientific basis.

Clifford (1973) has documented in detail the forlorn “history of the impact of research on teaching.” That history is a record of premature hopes dashed upon the realities of inadequate scientific bases. Educational innovations can indeed spread and become widely adopted—often to an extent and with a rapidity unjustified by the scientific basis for the innovation. The Roman-candle history of teaching machines (Markle, 1976) provides just one example. But more solidly established bases for change in teacher education in the application of scientific knowledge about teaching—can lead to a happier history. Teacher education should rise to a wholly new level as the scientific basis of the art of teaching becomes stronger.

KNOWLEDGE THAT vs. KNOWLEDGE HOW

It is important at the outset to make clear the need for knowledge of a new kind of relationship if teacher education is to apply what we have by way of a scientific basis for the art of teaching. This new relationship is one between teacher education policies, procedures, and techniques, on the one hand, and teaching methods and styles, on the other. Until now we have been concerned with teacher behavior—in all its ramifications, including teacher–pupil interaction and the creation of classroom environments—as the independent variable. But when we come to teacher education, we must look upon teacher behavior as the dependent variable.

Further, we are not so much concerned here with the teacher’s “knowing that” as with his or her “knowing how.” This distinction, made by the analytic philosopher Gilbert Ryle (1949), refers to the difference between being able to state factual propositions and being able to perform skills or operations. The one kind of knowledge does not necessarily follow from the other. For example, we may know that reinforcers strengthen responses but not know how to reinforce a pupil so as to strengthen the child’s tendency to participate in class discussions. Similarly, we may know that criticism in very small amounts may be good for the achievement of more academically oriented pupils but not know how to limit our criticism to those small amounts for that kind of pupil.

Much of the teacher education program is given over to providing teachers with a great deal of knowledge that certain things are true: in the subjects to be taught; in the historical, philosophical, social, and psychological foundations of education; in the curriculum and instruction of various subject matter fields; and so on. This kind of knowledge is acquired by prospective teachers in the courses taught by teacher education faculties, with all the paraphernalia and methods used in college teaching in general. For the most part, this aspect of teacher education has proceeded along much the same lines as those that have been followed in courses in the sciences and humanities—in English, history, philosophy, chemistry, or mathematics—at the college level.

In recent years, however, an additional approach toward helping teachers know and understand concepts has been used. This is the “protocol materials” approach. It consists of developing films or videotapes to be viewed by the teacher. The materials show instances, occurring in real or almost real settings, of particular categories of teacher behavior (e.g. approving or probing). After viewing the materials, the teacher should be able to recognize instances of a particular category and to categorize occurrences in real classrooms appropriately.

In one program for developing protocol materials, Gliessman and Pugh (1976) produced films showing instances of the concepts of approving, disapproving, probing, informing, reproductive (lower-order) questioning, and productive (higher-order) questioning. Shown to students in
educational psychology courses, the films raised scores on tests of ability to categorize these behaviors and received favorable ratings from the instructors and their students. It seems clear that protocol materials can go a long way toward reducing the hitherto almost total reliance on words as the medium by which teachers are helped to understand the concepts and phenomena entailed in their work.

When it comes to providing prospective or already employed teachers with knowledge how, we know that practice is required—as another analytic philosopher, Jane Roland (1961), has pointed out. “Jones could not know how to swim or speak French unless he had at some time practiced swimming or tried to speak French” (p. 61). It is this realization of the need for practice that has led from the very beginning to the inclusion in teacher education programs of opportunities for practice teaching.

Yet common sense and research results agree in finding that practice alone is not enough. If it were, teachers would automatically improve in performance as they gained more years on the job. But the fact is that at least nine studies have shown only a very low correlation, if any, between years of teaching experience and the average achievement of the teacher’s students (Rosenshine, 1971, pp. 201–205).

Those studies were made with teachers already in service. What about the practice of budding teachers? Here the practice is accompanied by the observation, guidance, and advice of the regular classroom teacher, who provides a model as well—one from which the student teacher can presumably learn.

Student teaching has been the subject of much thinking, writing, and even some research over the decades. In general, it has been considered to be the single best, though far from faultless, component of teacher education programs. It has often been indicted as too unsystematic or unplanned, as unmanageable in its complexity, and as too much at the mercy of the idiosyncrasies of the cooperating and supervising teachers. Some appraisals have shown that student teachers hardly change their ways of teaching at all, from the beginning to the end of the student teaching period—and even that their attitudes and behavior tend to deteriorate, at least in the view of those who value nonauthoritarianism and nonpunitiveness in teaching.

It has been demonstrated that skill in simple and complex motor tasks continues to improve over hundreds and even thousands of trials (Hudgins, 1974). Apparently, knowledge of results continues to operate to improve motor skills even over protracted practice. In student teaching, however, such feedback or knowledge of results seldom comes through clearly or quickly enough to improve performance. The feedback may be delayed for days or weeks, or never appear at all.

Hudgins (1974) has derived from research on the learning of complex skills certain principles that should apply to the acquisition and use of teaching skills, such as the teaching of concepts (Clark, 1971). In teaching concepts, the teachers should first assess the pupil’s preinstructional knowledge. Second, the teacher should define the concept and offer clear, positive instances along with indications of their critical characteristics. Third, the teacher should gradually mix negative instances into the examples, asking the student to indicate whether each does or does not meet the criteria of the concept, and give the student feedback after each response. Finally, the teacher should evaluate the student’s learning of the concept.

To prepare teachers to carry out such steps, teacher education should provide for the teacher’s (a) learning the general model of the teaching skill; (b) practicing the skill in a self-contained setting, one that is easily arranged and does not require students and supervisors but does provide the teacher with feedback; and (c) practicing the skill in the actual classroom. Using this conception of teacher preparation led Hudgins to a restatement of the already well-established concept of self-contained materials for teacher education—a concept we shall consider in various forms. Here we note only that this concept represents a major effort to overcome the limitations of the student teaching arrangement that was for too long the sole vehicle of practice for prospective teachers.
TECHNIQUES FOR CHANGING TEACHER BEHAVIOR

Thus we see that the limitations of student teaching made teacher education receptive when
alternatives began to be offered. The time for more varied and manageable approaches had
come.

Microteaching

In the 1960s, teacher educators fell hungrily upon the innovation called microteaching. Micro-
teaching caught on rapidly. Within a few years it was being used, in one form or another, in 176
programs for educating secondary school teachers in the United States (B. E. Ward, 1970). I am
also aware of its being used in several other countries, including Australia, Canada, England,
West Germany, Israel, Nigeria, and Sweden.

As is well known, microteaching is scaled-down teaching—teaching conducted for only five or
ten minutes at a time, with only five or ten students, and focused on only one or a few aspects of
the teacher’s role. The teacher tries, say, reinforcing participation or making an assignment,
rather than undertaking the whole of what a teacher does, in all its multifaceted complexity, with
a class of 30 for a whole period of instruction.

The advantages of microteaching become evident as soon as one encounters this intriguing
idea. Such an arrangement is at the least more manageable and controllable. It does not take up
whole hours and classes in order to give the neophyte an introduction to teaching. It does not
induce the anxiety that accompanies facing a whole class for a whole period. It allows concentra-
tion on one part of teaching at a time—just as the violinist can play the same few bars again and
again.

Not only was microteaching widely adopted; it was closely studied. The technique lends itself
to easy variation and manipulation, and many of the possibilities were quickly tried. For example,
the value of providing the microteaching teacher with a model was investigated, and different
kinds of models—live, videotaped, or merely printed—were compared to determine their
effectiveness in promoting the teacher’s acquisition of a given skill. Also, the feasibility of teach-
ing peers rather than actual pupils was investigated. The number of pupils taught was varied. The
kinds of supervision and feedback provided the teacher were studied, particularly as to the value
of videotaped feedback. And the interval between the first and second microteaching sessions
was permitted to range from a few minutes to a week.

The results of many of these investigations have been reviewed by Turney, Clift, Dunkin, and
Traill (1973), writing in Australia. I mention this work only to indicate the enthusiasm and industry
that greeted this first major departure from the traditional sole reliance on student teaching as the
vehicle by which the prospective teacher could get some practice. For our purposes, let it suffice
to say that microteaching has generally been found to be effective in the sense that teachers do
exhibit the kinds of behavior at which the microteaching is aimed—not only in the hours or days
immediately following the microteaching but in the subsequent months and at the end of the first
year of actual teaching as well (Trinchero, 1975). Compared with traditional observation and
teaching experience, microteaching produced teachers judged to have higher degrees of
competence and more favorable attitudes toward their teacher education programs.

Nonetheless, microteaching research has not yielded many firm conclusions concerning the
value of the many variations possible within this approach to teacher practice. It may be that such
research has erred in regarding the technique too much as a vehicle for increasing knowledge
how and too little as a means for influencing knowledge that. Such a conclusion seems to follow
from the studies conducted and reviewed by MacLeod and McIntyre (1977). Their work led them
to a new rationale for microteaching as a teacher education technique—a rationale that
emphasizes teachers’ cognitions. Microteaching can thus be regarded as primarily a way of
influencing cognitive structures that are important in teaching. Such structures, they held, should give teachers conceptually simple guides by which to govern their behavior in the hundreds of interpersonal interactions occurring in a day’s classroom work.

**Minicourses**

Microteaching was developed primarily for use in preservice teacher education. It was relatively unwieldy in inservice teacher education, where supervisors and videotape recording machine operators were usually hard to come by. What was needed was a relatively self-administrable version of the microteaching idea. This was soon forthcoming in the form of Minicourses (Borg, Kelley, Langer, & Gall, 1970). Minicourses are packages of materials, including manuals, self-administered tests, and films, intended for use with videotape or audiotape recorders in rooms and with pupils furnished by the school.

With one typical Minicourse the teacher can acquire training in “Organizing Independent Learning: Primary Level.” First, the teacher reads about a set of skills in the teacher’s handbook; second, she views a film explaining and illustrating those skills; third, she plans and teaches a lesson in which she practices the skills; and fourth, she evaluates her lesson. The practice is performed both in a microteaching format, with only three or four pupils outside the regular classroom, and in the regular classroom with the entire class. This Minicourse takes about an hour a day for 16 days over about a four-week period. In general, the course is aimed at helping teachers to establish with pupils the concept of working independently, to give pupils facility in solving problems that arise during independent work periods, to develop appropriate expectations about the promptness or delay of teacher response to pupil work, and finally to combine independent work, problem solving, and delayed response into a learning environment that facilitates independent activity and small-group instruction.

All in all, about a dozen Minicourses have been developed, tested, and marketed. The testing consists of an experiment in which teachers are first observed to determine the preexisting level of the teaching skills at which the Minicourse is aimed. Then the Minicourse is individually self-administered by the teachers. The teachers are observed again by trained observers who determine the quality of the behaviors in the teacher’s actual classroom some time after the end of the Minicourse.

Borg (1972) carried out what may be the most convincing demonstration of Minicourse effectiveness thus far. Among the behaviors influenced were “Redirecting the same question to several pupils,” “Framing questions that call for longer pupil responses,” “Seeking further clarification and pupil insight,” and “Not repeating pupil answers.” He made videotape recordings of each of 24 teachers before, immediately after, 4 months after, and 39 months after training. Analyses of the recordings showed that the Minicourse significantly changed most of the 10 question-asking behaviors that the Minicourse was intended to influence. Borg concluded that “after 39 months, the performance of the subjects was still significantly superior to their pre-course performance on 8 of the 10 behaviors that were scored” (p. 572). It might be objected that the teachers knew their behaviors were being recorded and hence behaved as they had been influenced to behave only to please the investigator. But this possibility seems remote simply because the behaviors cannot be turned on and off that easily. It seems improbable that teachers could exhibit these 10 behaviors unless the behaviors had become fairly well established in the teacher’s normal practice.

**Other methods of changing teacher behavior**

With microteaching and Minicourses, teacher educators acquired tools that seemed to have demonstrable effectiveness in improving the teacher’s “knowledge how.” These approaches
received the widest attention and were subjected to the most research. But they were not the only procedures that appeared on the teacher education scene during the sixties and seventies. For example, Flanders (1970) had accumulated much evidence about teachers who learned and used his interaction analysis categories to observe and analyze their own behavior or who received information about their behavior in terms of these categories. Such teachers usually made some successful attempt to change their behavior to make it accord more closely with their own previously unarticulated conceptions of desirable teaching.

Similarly, Wagner (1973) compared the effectiveness of microteaching and cognitive discrimination training in bringing about student-centered teaching on the part of undergraduates (prospective teachers). The discrimination training consisted of presenting the undergraduates, four at a time, with 33 recorded teacher replies to student comments. The prospective teachers had been supplied with a brief description of six subcategories of teacher replies (namely, “asking for clarification,” “restating,” and “using students’ ideas”—all considered to be parts of student-centered teaching—and “asking a directive question,” “arguing,” and “ignoring”—all considered to be aspects of teacher-centered teaching). The undergraduates coded the taped teacher responses one at a time and then, after each coding, were told the correct answer and given a short explanation. The training lasted about 30 minutes. Another group of undergraduates engaged in microteaching for about 30 minutes. Subsequently, both groups of undergraduates prepared and taught a new lesson. It turned out that the discrimination training was significantly more effective than the microteaching in bringing about student-centered teaching. Thus, learning to discriminate was sufficient to bring about behavioral change. In this instance, and perhaps in many others, the more elaborate microteaching procedure could be replaced by this less expensive kind of training.

Another demonstration of the possibility that simple techniques can change teacher behavior was provided by Good and Brophy (1974). They used a single interview to provide a teacher with feedback based on observations of the teacher—feedback intended to help change teacher behavior toward selected students. Each teacher was at once informed and advised about his or her own behavior toward various pupils. Thus in making suggestions for improvement the authors were in effect saying, “You are doing a fine job with Mary; now try to do the same kinds of things with Jane.” This is much less threatening and more acceptable than “your way is wrong, do it my way” (p. 291).

Using this approach, Good and Brophy identified pupils who participated much less than the average and also pupils who seldom were encouraged by the teacher to make a second or an extended response to a question. The teachers were given the names of these pupils as well as the names of pupils whom the teachers were treating appropriately. As a result of the interview, the teachers agreed to seek responses more persistently from the appropriate pupils and also, although less readily, to call more frequently on pupils who were infrequent participants and to initiate more private interactions with them. Subsequent observations in each classroom showed that the teacher had changed substantially in the directions intended.

There is another way to change teacher behavior that is even less expensive than the discrimination training provided by Wagner or the interviews conducted by Good and Brophy. The technique has been used, especially at the college level, and found to be moderately effective. It consists of using students’ descriptions of their teachers on rating scales as feedback to the teachers. Such feedback has been used with sixth-grade teachers given their pupils’ ratings (Gage, Runkel, & Chatterjee, 1963), with elementary school principals given their teachers’ ratings (Daw & Gage, 1967; Bums, 1977), and with social studies department chairmen given the department members’ ratings (Hovenier, 1966).

Discrepancy influences the technique’s effectiveness. Thus, Centra (1973) showed that the feedback to teachers of college students’ ratings produced change in the teachers’ behavior only when there were marked discrepancies between the teacher’s self-rating, or self-perception, and
the students’ ratings. Similarly, the greater the discrepancy between teacher’s ratings of their ideal and their actual department chairman, the greater the change in the department chairman’s behavior as a consequence of the feedback, as compared with the change in a group that did not receive the feedback (Hovenier, 1966).

Such ratings are altogether inexpensive. The technique requires no interviews or observations by professional staff whose salaries must be paid. Thus the feedback of students’ ratings can be regarded as a feasible approach to teacher change—but only under certain conditions. For one thing, the pupils must be mature enough to make usable and reliable ratings; the fifth or sixth grade is probably the lower limit in this sense. Second, the teachers must be motivated to change by virtue of their respect for student opinion. Third, as McKeachie (1976) has pointed out, teachers are more likely to change if they receive initial ratings that are moderate rather than extremely high or extremely low. McKeachie considers this finding to be consistent with achievement motivation theory—theory that predicts greater success or change when expectations are neither too high to be realistic nor too low to instigate action. Finally, the feedback may be expected to have an effect only when the teacher has the indicated changes in behavior within his or her repertoire of behaviors—in other words, when the teachers can change in the desired direction if they want to. Here, the microteaching and Minicourse techniques could be useful in equipping teachers with desired ways of behaving that they do not already possess.

One last approach seems worth mentioning if only because it rests on the ever-attractive conception of teaching as a performing art. What Stanislavski did to help his actors realize their roles may help teachers comprehend and enact theirs. Travers and Dillon (1975) have worked on this appealing idea. They summarized Stanislavski’s method and then presented scenarios for careful study by future teachers. They intend the study to consist of more than reading—the student should analyze the role characteristics, reread the scenario, put himself into the teacher’s shoes, act out and speak the parts, and try to experience the appropriate feelings and ideas. Rather than focusing on the teacher’s observable performance, this approach emphasizes “inner behavior.” It assumes the correct inner behavior will be reflected in appropriate “outer behavior.”

In another part of their treatment, Travers and Dillon seem to contradict themselves by telling teachers that, if they will relax their muscles (outer behavior), they will reduce their feelings of tension and anxiety (inner behavior). Here the outer behavior is assumed to control the inner. Also, the authors offer no research evidence that their techniques work. Nonetheless, if it can be put into forms that can be experimentally tested, the idea of training teachers as if they had much in common with actors seems to be worth trying.

THE FIELD OF TEACHER EDUCATION PRODUCTS

Let us turn now to a more general view of the effort to apply a scientific basis for the art of teaching to teacher education. This view takes in the field of teacher education products. These are materials packaged in a form that makes them transportable and relatively self-administrable for use in changing and, it is hoped, improving teaching in some way. Such products have been developed by the hundreds during the last decade, largely as a result of the emphasis on developmental work by the Federal government’s Office of Education and National Institute of Education. That emphasis influenced university research and development centers, regional educational laboratories, and many other organizations and workers to produce curriculum packages and materials to help teachers and administrators. The whole enterprise was an attempt to make readily available and highly usable the ideas and techniques that educational research and development workers had formulated. In the past, these ideas had usually gone unused and neglected by the practitioners to whom they could conceivably be helpful.
The Stanford catalog

The teacher-training products became so numerous that several catalogs of these materials appeared. Finally, the Program on Teaching Effectiveness (1974) at Stanford, in order to meet its own research and development needs, compiled a master catalog stored on computer tape. That catalog identified and described more than 800 products. A teacher-training product was defined as material intended to equip teachers with skills, or knowledge of how to do certain things, rather than merely knowledge that certain things are true. As we put it in a monograph describing the field, teacher training products must require the trainee to be active, in the sense of performing, practicing, or trying out the skills to be acquired. Such a requirement rules out training materials that merely ask the trainee to receive information through reading, listening, or viewing.

(Program on Teaching Effectiveness, 1974, pp. 3–4)

The Stanford catalog described the hundreds of products in terms of nine dimensions:

1. The product’s subject matter specificity. (Did it apply to the teaching of English, mathematics, science, social studies, or school subjects in general?)
2. The target audience. (Was the product intended for preservice trainees, inservice teachers, or both?)
3. The grade-level specificity. (Was the teaching skill pertinent to early childhood education, to the high school level, to something in between, or to all levels?)
4. The so-called target outcome. (Which aspects of teaching—such as planning, presentation, interaction with pupils, attitude toward teaching, or the teacher’s self-concept—was the product concerned with?)
5. The target outcomes for students. (Which of various kinds of cognitive and social-emotional outcomes?)
6. The training situation. (What materials were provided with the product and what materials and equipment had to be provided by the user?)
7. The time and number of persons required to administer training with the product. (How many trainees could use the product at one time?)
8. The kind of practice provided. (Was it paper-and-pencil exercises, or classifying incidents in a film, or playing a simulated teaching game, or teaching actual students?)
9. The phase of teaching in which the acquired skills would be used. (Did the training apply to the teacher’s work before, during, or after interaction with students?)

The NEA/Far West Laboratory Project

The main purpose of the Stanford catalog was to determine in detail what was already available in order to plan the work of the Stanford Center’s Program on Teaching Effectiveness. For this reason the catalog was not readily usable by teachers and teacher educators who were interested in considering the products. The need for putting the information into a more usable form eventually led to a new project conducted by Robert McClure and Robert Luke of the National Education Association with the support of the National Institute of Education and the collaboration of Beatrice Ward of the Far West Laboratory for Educational Research and Development. In this “Pilot Project on Practitioner Selection, Use and Critique of Inservice Education Projects” (McClure, 1976), many products were examined by teachers, teacher educators, and other potential users. McClure characterized
the products as ranging from simple to complex; as providing either individual or large-group instruction; as ranging from cheap to expensive; as using either a single medium or several media; as ranging from homemade to “slickly professional”; as being subject-centered or process-oriented or both; as being oriented toward all levels from early childhood education to college and adult education; as ranging from those that offered undocumented, simply derived claims for effectiveness to those that had been subjected to rigorous field tests; and as varying between empirically based and theoretically based.

From working with practitioners, McClure and his coworkers gained the impression that most teachers were unaware of the existence of the products. Further, it seemed that the most successful products clearly matched teachers’ stated needs in such activities as individualizing instruction, managing classrooms, or teaching reading. These products could be used without an outside resource person, could be used and completed over a period of several weeks, employed methods other than merely presenting reading matter, and were attractively but not expensively packaged. Some persons who knew about the products rejected them on the grounds that they imposed others’ views of teaching or were unrelated to a local problem. But others viewed the products as “one resource that can help to solve some persistent problems with inservice education” (McClure, 1976, p. 15). This was the view adopted by the NEA/Far West Laboratory Project.

What do these products consist of? The NEA/Far West project described them in terms readily understandable by teachers. Let us consider products intended to help teachers in motivating students, since that problem received the highest average rating for level of interest in an NEA Assessment of Teacher Inservice Education Needs conducted in 1975. Student motivation is one of four categories into which the NEA/Far West project has grouped the more than 50 products it has described in detail. (The other three categories were individualizing instruction, language arts, and classroom management.)

One product, entitled “Motivation Theory for Teachers,” was developed in 1967 by Madeline Hunter. It consists of a film and an optional programmed book aimed at interpreting motivation theory so that it can be useful in the daily decisions of teachers. The film deals with six factors that can influence motivation: anxiety in the form of concern for the task; the interest of the task; the feeling tone of the task; the level of difficulty of the task; knowledge of results; and intrinsic rewards. The describer’s critique of the film states that it “is appropriate to the objectives stated at the beginning of the film. The technical quality is good . . . The content of the film appears to be accurate and socially fair.”

A second product in this category is entitled “Individually Guided Motivation.” It was developed at the Wisconsin Research and Development Center for Cognitive Learning, under the direction of Herbert Klausmeier. It deals with four motivational procedures to be used with elementary school children: adult-child conferences to encourage independent reading; teacher-child conferences for goal setting; older children tutoring younger children; and small-group conferences to encourage self-directed desirable social behavior. The product consists of a textbook to be studied and five films to be viewed and discussed by the teachers. It requires five two-hour sessions or a two-day workshop. Large-group sessions are used to communicate information, show films, and administer self-assessment exercises. Large- or small-group sessions are used to criticize and apply information, discuss practice exercises, and engage in role playing.

This pair of descriptions must suffice to illustrate what is meant by teacher-training products. In general, they have the advantages and disadvantages of textbooks or any other standardized set of instructional materials. The advantage is that they can incorporate more careful thought, planning, and scholarship than most teachers or teacher educators can muster when left to their own resources. Their disadvantage is that they cannot be custom tailored to the needs and capabilities of each teacher who may use them. Thus they run the risk of missing the mark for a particular teacher.

Nevertheless, teacher-training products deserve to be better known and more extensively
tried. Toward that end the NEA group, under the direction of Robert Luke, has organized a “Project on Utilization of Inservice Education R & D Outcomes.” The project serves teachers and other local users in approximately 80 local education associations and school districts in 16 states across the country. It is intended to assist teachers in identifying problems in teaching the basic skills, to build an information system on training products aimed at improving teaching in the basic skills, to assist in setting criteria for selecting products, and to provide help in adapting the products to local conditions. Descriptions of products are kept in central files at the NEA. An information specialist is available via a toll-free telephone line to help users track down the products that seem most promising. All in all, the system is administratively elaborated and coordinated in such a way that the obstacles of ignorance and information lack should be substantially overcome. Then teacher-training products can be given the fair try they deserve.

TEACHER CENTERS

It should be obvious by now that more is involved in teacher education, both preservice and inservice, than a scientific basis for the art of teaching. We need more than the knowledge and tools that will make teacher education procedures influence teacher behavior and, in turn, make teacher behavior contribute more to student achievement and desirable attitudes. Teacher education products of the kind just described are in themselves only part of what is needed. Beyond them organizational and administrative arrangements are needed to bring together productive combinations of leadership, personnel, time, and money.

One idea for organizing such combinations is the teacher center. As is well known, the idea was born in England (see Thornbury, 1974). It was brought to this country by Americans who saw it there and liked what they saw (Rogers, 1976). In brief, teacher centers are places where teachers can come together with other teachers, and perhaps with other useful persons, such as professors, to do things that will help them teach better.

It would not be appropriate to my topic to attempt a full-scale analysis of the alternative kinds of teacher centers that have been proposed and of the political pulling and hauling that have accompanied their development in this country. These matters have been discussed by Eugenia Kemble (1973) from the point of view of the American Federation of Teachers. She has quoted both the AFT’s David Selden and the NEA’s David Darland as being opposed to the kind of forced and mandated inservice teacher education that teacher centers would presumably replace. To my mind also, teacher centers should be initiated and controlled by teachers. Other kinds of participants, such as administrators, parents, and professors, should come to them only by invitation. Just as practitioners of medicine, law, and engineering take responsibility for their own continuing education, so teachers should have the right to do the job for themselves. This proposition seems to me to follow from any decent respect for the professionalism of teachers.

Teacher-governed teacher centers should learn about teacher education products and procedures as these may commend themselves. Thus these approaches should get a fair chance to prove themselves; and that is all that their developers should ask. In short, these ways of applying knowledge about teaching ought, it seems to me, to stand or fall on their ability to impress teachers favorably and to improve teaching, with only such consultation with research workers and other scholars as teachers may see fit to invite.

Teacher centers that focus on teacher education products have been termed “behaviorally oriented” by Feiman (1977), who also identified two other kinds: the humanistic and the developmental. Both of these involve teachers in less structured activities. The humanistic centers try to help teachers share their own expertise with one another in a secure, supportive, and informal atmosphere; teachers adapt materials on display and talk about how things were made. The developmental centers use advisors and curriculum workshops to get teachers to think about the
ways in which they organize their experience and their classrooms and to reexamine their beliefs and teaching behavior.

Each of Feiman’s three kinds of centers seems to have advantages. It will be regrettable if the “ideological” differences between the types prevent centers from gaining the advantages of all three types: the structure and focus of behavioral centers using teacher education products; the teacher-centeredness and informality of humanistic centers using unprogrammed encounters; and the conceptual orientation of developmental centers providing advisory services. If I have emphasized teacher education products, it is only because they have most obviously represented ways of applying a scientific basis for the art of teaching. But teacher centers can make those applications in other ways, such as discussion and encounter groups, workshops, advisory services, and the simple process of helping teachers talk to one another.

THE CONNECTIONS BETWEEN TEACHER EDUCATION AND EDUCATIONAL OUTCOMES

Two kinds of causal connections are part of the logic of teacher education. The first kind was considered in Chapter I, where it was argued that something is indeed known about relationships between teaching behaviors and methods, on the one hand, and pupil achievement and attitudes, on the other. The second kind of connection is that between teacher education procedures and teacher behaviors.

Now there ought to be a good connection between the two kinds of connections. That is, (a) teacher education should be aimed at producing (b) the kinds of teacher behaviors that have been shown to be related—preferably causally related—to (c) valued kinds of student knowledge, understanding, sensibility, and attitude. Then the $a \rightarrow b$ connections would contribute to achieving the $b \rightarrow c$ connections.

The hiatus between the two connections

Strangely enough, the work on each of the two kinds of connections has proceeded almost completely independently of the other. Developers of teacher education procedures have gone ahead with their $a \rightarrow b$ work without waiting for empirical evidence on $b \rightarrow c$ connections—evidence that the kinds of teacher behaviors they were trying to bring about were indeed conducive to the achievement of educational goals. There has been too little unification of effort of the kind that would bring research and development on teacher effects, or the effects of different kinds of teacher behavior, into close contact with research and development on ways to bring about those kinds of behavior. In short, the right hand of research on teaching effectiveness has too seldom informed the left hand of research on teacher education of what it has been up to. In other words, we have not had enough $a \rightarrow b \rightarrow c$ research.

An example of this kind of divorcement can be seen in the work on teachers’ questions. Research has thrown serious doubt on the desirability of so-called higher-order questions—questions that call for thinking and problem-solving rather than mere recall. A fair number of correlational studies and experiments (see especially Rosenshine, 1976, pp. 355–356; Gall, Ward, Berliner, Cahen, Crown, Elashoff, Stanton, & Winne, 1976; Program on Teaching Effectiveness, SCRDT, 1976) have failed to show what many educational thinkers had expected, namely, that teachers who ask more “thought” questions produce pupils with better understanding of the subject matter. Indeed they have more often shown the reverse. Higher proportions of lower-order, or recall, questions have usually been accompanied by higher pupil scores on tests of both knowledge and understanding of the subject matter. The research is not yet conclusive on this matter, and more sensitive forms of both the questioning and the achievement variables may
eventually yield the results that many writers have led us to expect. Nonetheless, we do not at present have any firm empirical basis for advocating that teachers ask more higher-order questions than they presently ask (a rather low proportion).

The explanation may well be that the give-and-take of the classroom recitation is no place for higher-order questions. Such questions, by definition, require deliberation, which takes time. And pupils feel too harried by social pressures in this setting to benefit from the opportunity to think. This explanation implies that higher-order questions should improve understanding when encountered in the course of reading prose, in a setting congenial to quiet deliberation. And this implication is supported by evidence that “higher-order inserted questions are of greater benefit than factual ones” (Faw & Waller, 1976, p. 712).

Notwithstanding this state of affairs with respect to higher-order questions in classroom discussions, teacher education research and development have proceeded to develop techniques, such as Minicourses, for instructing teachers to frame more “questions that require the pupil to use higher cognitive processes” (Borg, 1972). Many other objectives of teacher education have also been adopted and acted upon prior to any demonstration that the particular kinds of behavior were desirable in the sense of fostering achievement and desirable attitudes.

An illustration of unified effort

What is needed is work that unites the effort to show that a certain kind of teacher behavior is desirable with the effort to show that such behavior can be brought about through teacher education. Let me illustrate what is needed by describing an experiment in 33 third-grade classes conducted by the Program on Teaching Effectiveness at Stanford University. Put very briefly, the aim of the experiment was to determine whether teachers instructed to behave in certain ways produce pupils with higher levels of achievement and more desirable attitudes than do teachers who have not received such instruction. The noteworthy feature of the experiment in relation to the point concerning unification of effort is that the teacher education objectives were derived in detail from the results of previous correlational studies. The results of those studies were examined, variable by variable, in terms of (a) the exact operational definitions of the teacher behaviors observed, (b) the correlations of those behaviors with adjusted measures of pupil achievement in reading, (c) the average and the variability across teachers of the frequencies of the given kind of teacher behavior, and (d) the implications of the empirical findings for what might be considered desirable in teacher education, given the criterion of pupil achievement in reading (see Table 2, in Chapter 1).

This kind of detailed sifting of the evidence concerning hundreds of teacher behavior variables in four recent, relatively large-scale correlational studies provided the basis for the formulation of the “teacher-should” statements presented in Chapter 1. That formulation, in turn, was expressed in five sets of reading matter, presented at the rate of one per week to the teachers in the instructed group. The instructed teachers were themselves divided at random into two subgroups. One subgroup received the instruction in a “minimal” form consisting merely of the reading matter and self-scored quizzes on the reading matter. The other subgroup received the instruction in a more traditional, and much more expensive, workshop format. These teachers not only read the material and took the quizzes but they participated in weekly group meetings with an instructional staff. At these meetings, the teachers engaged in role playing, viewed videotape records, and discussed the content and problems considered in the teacher education materials.

This experiment illustrates the kind of linkage between teacher education and teacher effectiveness research that seems to be obviously logical and desirable. Yet only a few examples of it are known. Still fewer of these have developed the linkage with detailed attention to the correlational findings on teaching effectiveness.

It should also be noted that each of the teachers in both the instructed and the uninstructed
groups was observed in detail for 18 full school days during the school year—that is, one day every one to three weeks before, during, and after the teacher education program. And, of course, the pupils and their teachers took batteries of tests of cognitive and noncognitive variables at the beginning and end of the school year.

The broad purposes of the experiment should by now be obvious: It is intended, first, to determine whether teacher behaviors that correlate with pupil achievement have causal efficacy in improving pupil achievement. It will also determine how a cheap and easy way of instructing teachers compares in effectiveness with one that requires a professional and hence expensive teacher education staff.

In summary, to restate the main proposition of this chapter, there are many ways to give teachers knowledge of how to teach. These ways, in all their variety, have been found to work in the sense of getting teachers to behave in ways congruent with the aims of the teacher education effort. Accordingly, the tools needed to apply what we know of a scientific basis for the art of teaching are relatively well in hand. They are being further developed and tested in field programs, such as that of the NEA, and they should receive fair consideration in the teacher centers of the kind being advocated by the AFT. The main need in this field is a closer connection between the work of the teacher education researchers and that of the teacher effectiveness researchers. That closer connection can be seen in efforts to use the findings of correlational studies in experiments whose effects on both teacher behavior and student achievement and attitude are determined.

NOTE

1 The citations in this chapter are located in the general reference listing at the end of The Scientific Basis of the Art of Teaching (N. Gage, 1978).

An argument for complexity in studies of teaching and teacher education

Michigan State University

ABSTRACT

This article borrows an analogy from Michael Cole’s Cultural Psychology: A Once and Future Discipline. A man loses his car keys and searches unsuccessfully for them only in the area illuminated by the streetlight. Cole urged psychology to study thought by illuminating human activity in cultural and historical context. Lanier and Shulman similarly urged the study of teaching as multidisciplinary research. An applied field, our research is responsive to problems of practice. However, when these problems are framed rhetorically as crises, we are apt to respond to their urgency by seeking simplicity, authority, and order in our research. Paradoxically, this move reduces the sources of light diverse research traditions and genres can offer. We should resist (a) pitting approaches to research against one another, (b) privileging approaches merely because they are compatible with the language of policy, (c) accepting uncritically any approach to research, and (d) disregarding research emphasizing local knowledge.

It takes a lot of variables to describe a man, or for that matter a virus; and you cannot often usefully study these variables two at a time. Animate nature also exhibits very confusing instabilities, as students of history, the stock market, or genetics are well aware.

(Weaver, cited in Mead, 1976, p. 904)

The title of this article borrows a metaphor used by Michael Cole (1996) in his book Cultural Psychology: A Once and Future Discipline. Describing the historic “marginality of cross-cultural research to mainstream psychology” (p. 62), Cole commented,

Such a position is uncomfortably reminiscent of the man who searches for his lost car keys only within the arc of light provided by the street lamp, except that psychologists who fail to encounter culture in their carefully designed experiments declare, in effect, that the keys have ceased to exist because they are not under the lamppost.

(p. 68)

Cole urged “approaches that enlarge the ‘circle of light’ in which to look for the keys to relationships between culture and cognition” (p. 68) and illustrated with examples of psychological research taking into account the role of culture in human thought and activity. American
educational research in the 20th century is a child of the field of psychology. As such, it shares many of the challenges Cole described. Broadly speaking, research on teaching and teacher education is concerned with the study of mind, culture, and activity. Its focus is the nexus of these in what Erickson (1982) called “taught cognitive learning.”

A hallmark of our species, explicit teaching is a skilled craft as well as a cultural tool. By means of teaching, knowledge is encoded, passed on, and transformed over time. This process of teaching operates in the life history of the individual as well as the history of a society. It acts reflexively to conserve a society’s norms and standards while enabling individuals’ agency and the possibility of social transformation (Eisenhart, 1995). In making teaching and teacher education topics of research during the 20th century, scholars responded to optimism that social science could be mobilized to serve human needs and problems. Their efforts can usefully be thought of in terms of Cole’s (1996) metaphor.

Social scientific efforts to understand the complexities of teaching and teacher education—for purposes of improving pupil as well as teacher learning—add more light to a complex subject. However, applied research does not occur in a vacuum. As a social, discursive practice in its own right, research is sensitive to the ebb and flow of resources and problems in society’s history and its politics. Thus, what counts as research for informing policy and practice in teaching or teacher education shifts with perception of the problems it might inform, the availability of resources to support it, and the particular interests and values of powerful practitioners and policy makers who use it in their decision making. The remainder of this article is about the light shed by research on the complexities of teaching and teacher education in our time. It is also about circumstances that change the light by which researchers view teaching and teacher education. The article closes with some cautionary thoughts about the tendency to narrow the scope of research to focus only on the spaces immediately relevant to a pressing problem framed by powerful consumers and benefactors of research.

CONSIDERING COMPLEXITY

While on sabbatical in the mid-1980s, I audited an inquiry course at Harvard University taught by Eleanor Duckworth. In it, fledgling researchers were treated to many intriguing and challenging activities. We tracked the behavior of the moon as it made its way through a month of skies. We responded to poems and paintings. We played with mirrors to figure out how they work. We investigated permutation, combination, and probability by sorting poker chips and jellybeans. I enjoyed this new and different way of thinking about learning. But I admit to having shared a bit of anxiety with the bright, earnest doctoral students in the class. What, we wondered, does all this have to do with educational research?

With characteristic ability to turn academic assumptions on end, Duckworth (1991) addressed this question in an essay titled “Twenty-Four, Forty-Two, and I Love You: Keeping It Complex.” In it, she retold the following vignette:

My favorite radio show is “A Hitchhiker’s Guide to the Galaxy.” In one episode, a computer is built expressly for the purpose of answering the question, “What is the meaning of life, the universe, and everything?” When it is ready, they ask if it can answer that question. It says, yes, it can, but that it will take, as I recall, seven million years. They say, “Well, OK, go to it.” Seven million years later, whoever is around goes to learn the answer. The computer says that it does have the answer, but that it might be a little disappointing. “No, no,” they say, “go ahead, what is it?” “Forty-two,” the computer says.
Duckworth speculated, “Who knows? Maybe forty-two is the answer. But such an answer is of no more help to us than no answer at all. It does not speak to our level of interaction with the mysteries of our existence” (p. 7).

In the same essay, Duckworth (1991) offered another anecdote, this one from research conducted by Lisa Schneier, an urban high school teacher, in her ninth grade English class. Schneier described her students reading aloud the balcony scene from Romeo and Juliet. Taking Shakespeare’s difficult language in stride, they enjoyed acting out the parts. Schneier was aware from their intonation and gestures that they understood some but not all of what they were reading. The activity went so well that Schneier did not interrupt it for discussion. She reported, however, that our last Romeo of the day finally did interrupt it. We had started the scene again to give more readers a turn, and he had begun to wade through his first speech. In the midst of it, he broke off, shook his head impatiently, and turned to me. “He loves her. That’s what he’s saying. So why all that other stuff? Why not just say it? I love you!” [to the current Juliet]. There!” And then in a memorable tone, a mixture of humor, frustration, and honest confusion: “Why can’t he just say what he means?” (pp. 7–8)

Duckworth remarked,

Of course that’s what [Shakespeare] is saying: “what he means,” is complex. The words he chooses are the best he can choose to say what he wants to say, . . . There is a parallel here between a poet and a teacher: the universe is complex; science is complex; the poet’s thoughts and feelings are complex. “Forty-two” doesn’t do the trick . . . Nor, in this case, does “I love you.” (p. 8)

Sometimes the most helpful thing research can offer is thoughtful exploration of complexity. This may take a bit of both the computer and the poet. Margaret Mead (1976) alluded to this in her presidential address to the American Association for the Advancement of Science. Discussing the nature of what she called “a human science,” Mead described the dual forces at work in the scientific study of human understanding as “our capacity to explore human responses to events in which we and others participate through introspection and empathy, as well as . . . our capacity to make objective observations on physical and animate nature” (p. 905).

When we look back on more than a half century of research on teaching and a generation of research on teacher education, we notice scholars using both capacities. As they have done so, a variety of questions have been addressed, methods plied, and theories framed. Learning and practicing the craft of teaching has been researched, for example, as action that causes learning, a process of clinical decision making, negotiated sociolinguistic interaction, a force for cultural praxis, and much more. What does the accumulation of these studies tell us about teaching and learning? What does it tell us about our views of knowledge, our history and values as a society, our biases and blind spots, our work as researchers? Although these may not be questions our various audiences and benefactors ask us, they are questions we ask ourselves. Such epistemological stocktaking is different from other important scholarly responsibilities, such as the setting of standards for studies within any particular research tradition applied to understanding teaching or teacher education. Lave (1996) commented that self-examination concerning the origins, topics, and purposes of our studies is an important part of our scholarship precisely because our inquiry is not disinterested. Of this she wrote,

In education, in the social sciences, we have moved in the last quarter century from implicit
to explicit theory, increasing our ability to reflect critically on our own research practice. It seems crucial . . . to base the field of education on explicit accounts of its different theoretical perspectives.

(pp. 149–150)

Critical reflection on our own practice as researchers helps us assume responsibility for the questions we ask, the investigative methods we use, and the answers we devise. This self-monitoring activity is important for responsible research in an applied field such as ours. It helps us to be modest and circumspect in our claims to truth and reminds us to balance rigorous search for knowledge with responsiveness to problems of practice.

LOOKING FOR TEACHING

In the public schools of the late 19th and early 20th centuries, bureaucrats collected a lot of information about education. However, little of it explicitly and self-consciously addressed teaching, either its practice or the process of learning that practice. The history of teaching in the public schools of the United States offers a picture of a craft more or less taken for granted in the educational equation. Many teachers had only their own schooling to rely on as they faced their own pupils. In some cases, this schooling was limited to grammar school. In others, it also included “normal” training in teaching at the high school level. In a history of urban education, Tyack (1974) noted that “given the widespread assumption among school superintendents that teachers should be subordinate—should toe the line as their students did—this limited training was an advantage” (p. 59). Implicit in this belief was not only faith in emerging modern management techniques to regulate the behaviors of teachers and pupils but also a theory of mind in which neither teaching nor learning required more than prior experience and direct instruction in a limited range of contexts and contents. This led to both constancy in practice and a sense that teaching was determined and limited by social tradition (Cuban, 1984, p. 8).

Without deviation from this tradition, especially by innovation, there seemed to be little need to make teaching explicit in the recorded history of education in the early part of the 20th century. Thus, when Cuban (1984) studied the historical record of teaching in the early 20th century, he found little systematic documentation of its practice. However, he did find traces of teaching in anecdotal records of practice, especially in the ephemera of schooling such as classroom photographs, student reminiscences, school newspapers and yearbooks, reports of administrator visits to the classroom, and so forth. Apparently, teaching and teacher education were practices about which people held commonsense or folk theories and from which little in the way of complexity was expected. Still, Cuban acknowledged that like pottery shards to an archaeologist, the traces of teaching he accumulated and studied suggest a practice more complex than its record. And even with a richer data set from which to infer what teaching must have felt and looked like, Cuban asked, “How . . . can I capture only one slice of this whirl after it has disappeared?” (p. 8).

Figuring out how to study the “whirl” of classroom life and the teacher’s role was the focus of research on teaching as it came of age in mid-20th century. The rise of applied social science and the advent of electronic technologies for recording and reviewing classroom activity helped make the study of teaching a focus of research. It also afforded the means to experiment with different approaches to teaching. Early studies of teachers’ instructional behavior and its effects on pupil learning are reviewed in Dunkin and Biddle’s (1974) book, *The Study of Teaching*. The review emphasized the need for standards for research, stressing methods, guiding concepts, and data collection and analysis. Reflecting on the historic absence of a scientific study of teaching, they sought research-based knowledge on which to build effective teaching practice.
Moving teaching front and center, researchers hoped to make its study systematic and accountable not only to the social scientific community but, as an applied field, to decision makers responsible for designing teacher education programs and evaluating teachers' competency. In doing this, educational researchers joined others in what Cohen and Garet (1975) called the “applied social sciences.” Research on teaching and teacher education framed in the manner of natural science provides knowledge useful to administrators in that it offers information gathered objectively, reviewed by peers, and conducted rigorously and in sufficiently large populations to warrant general conclusions. What this ray of light illuminated was, in Dunkin and Biddle’s (1974) terms, “teaching as researchers have conceptualized it . . . the classroom behavior of teachers, the response of pupils, and the determinants and effects of these events” (p. 1). This orientation to research considered scientifically rigorous only those studies conducted in the “nomological tradition” (Wardekker, 2000). As such, the research they reviewed is premised on the idea that

acting means creating the conditions that enable a natural law to work in a way that will produce desired results. Thus, a teacher creates conditions under which learning processes, in a way, must happen. If students do not learn, that means that the right conditions for those processes were not created in that situation.

(Wardekker, 2000, p. 262)

This way of studying teaching is an outside-in process wherein the researcher, a classroom outsider, objectively records and analyzes behavior as data. Teacher thinking, what Clark and Yinger (1979) termed the “hidden world of teaching,” is not a focal problem in this research. Because it is not explicitly concerned with moment-to-moment judgments of the teachers whose actions are observed, teachers are not considered informants in the development of observational categories. Also framed out of view in this genre of research on teaching is close investigation of the nested, negotiated contexts—from interpersonal to social and historical—constraining teaching. Thus, absent in this view of teaching is investigation of teachers’ learning to act within and often despite vicissitudes of their working lives, cultural norms, and social institutions (Erickson, 1986). It is important to mention these limitations not because we should hold a study accountable for all of teaching’s complexities but to illustrate the need to look within and also outside the area illuminated by any single approach to research. Moreover, recalling Cole’s (1996) metaphor, the areas framed out of view, or left outside of the realm of inquiry, should not be assumed to be irrelevant to the inquiry.

The idea of applying the nomological paradigm to the study of social problems was ascendant at mid-century and remains extremely salient in contemporary research on teaching. Its research is especially useful and attractive to educational decision makers when they are designing and evaluating programs—a phenomenon of modern educational life. For example, Cohen and Garet (1975) characterized its authority in the eyes of policy makers in terms of its offering relevance, validity, and a “believable and consistent basis for social action” (p. 25). We can study human thought and activity in the light of this paradigm, seeking law-like generalizations about how teachers think and also what kinds of knowledge they need to make good pedagogical decisions. However, it is of limited use for purposes of understanding thoughtful action in context, a kind of research useful to teachers and administrators more locally.

To understand local knowledge in teaching and teacher education, we needed in-depth studies of individual teachers at work and of the variety of ways that teachers think about and do that work (e.g. Lampert, 1985, 2001). For example, we can use ethnographic research to study meaning in teachers’ thought and action, specifically, “what meanings people construct, how they construct them, and how these constructions guide their actions.” This kind of research, in what is called the “interpretive paradigm,” yields “a relatively loosely ordered collection of interpretive
schemes” often of interest and use to practitioners (Wardekker, 2000, p. 266). As we will see below, like the nomological paradigm, the interpretive paradigm has particular strengths and limitations. It illuminates different aspects of teaching and teacher education, and it does so in different ways and for different audiences and purposes.

In the 1970s, researchers tackled the problem of studying the local knowledge informing practice. Early on, the computer was viewed as both a metaphor and a conceptual model for studying local knowledge because it was able to make thinking both contingent and visualizable. Psychologists became interested in studying human thinking in context as “information processing” (Bruner, 1996). Yet when researchers used this metaphor to understand pedagogy, information processing needed to be further complicated to capture the reflexivity and indeterminacy of teaching practice (Spiro, Feltovich, Jacobson, & Coulson, 1993/1995). Of this Shulman (2001) recalled, I was struck by this incredible anomaly that while physicians were being studied as complex, autonomous, thoughtful, reflective, strategic problem-solvers, teaching was studied as if it were a series of mindless behaviors emitted by teachers in response to students as stimuli. It grew out of a totally different conception of the behavioral sciences. And so I began to raise the question: What would research on teaching actually look like if we thought about teachers with the same kind of respect and complexity that we hold for physicians and other professionals? (p. 11)

Because a teacher works with many students within emergent, normative, and negotiated settings, his or her knowledge is not simply instantiated in patterns of observed behavior, nor is it simply invisibly scripted and in the head. Instead, its norms are taught and learned, and they are shared sufficiently for us to recognize and even assess teaching. But these norms are not determinative. Teachers retain sufficient agency to act in new, creative ways. As such, teaching is both ordered and responsive to norms and standards and also improvisational and responsive to other participants (Gee, 1991; Shulman, 1986).

This way of understanding teaching and the approach to studying teaching that it implies are illuminated by sociolinguistic theory and its descriptions of communication as a cultural process in which language is grammatical, whereas its use (or speech)—constrained by grammar—is creative, context-sensitive, and thus both situationally appropriate and comprehensible (Cazden, 1986). Teaching, when viewed in this light, is a complicated craft to teach and learn. It requires skill, experience, mentoring, apprenticeship, and knowledge. The teacher as professional cannot be assumed to be prepared to teach simply because he or she has attended school as a pupil. Thus, the study of teaching and teacher education needs additional light from fields concerned with the social and cultural organization of thought and learning. Moreover, it needs a focus on the explicit preparation of teachers. In an introductory review of research in teacher education, Lanier (1986) noted that some of this research on teaching as a learned profession would necessarily be interdisciplinary and that it would need examination of the language, thought, and activity of the often overlooked “teachers of teachers” (p. 528).

Proposing multidisciplinary research on teachers’ clinical thinking, Lanier and Shulman (1975) sought to understand teaching complexity in ways that would inform the education of both pupils and teachers at the levels of both practice and policy. For them, absent a coherent, contextualized theory of teacher thinking in action, it would be difficult to envision a curriculum or means of assessment for teacher education that cultivated the habits of mind of a professional educator. Thus, seeking to complicate the prevailing nomological view of teaching, Lanier and Shulman wrote, It is not merely doing which defines teaching. It is knowing what to do and when to do it that
constitutes the clinical aspect of teaching and defines the features of teaching that serve as the subject matter for research on teaching as clinical work.

(p. B-I-6)

Some of the research genres applied to studying teacher thinking as clinical work have been in the nomological tradition (e.g. experimental, quasi-experimental, and correlational studies). Others have been interpretive (e.g. ethnographies, clinical interviews, and discourse analyses). Eclectic in style, research on teacher thought and action includes studies framed and conducted by university-based researchers and teacher educators (e.g. Brophy, 1989), practitioners (e.g. Ballenger, 1999; Lytle & Cochran-Smith, 1992), and teachers and university-based researchers working in collaboration (e.g. Raphael et al., 2001). These diverse inquiries share the idea that teaching is, in Bruner’s (1996) words, “inevitably based on notions about the nature of the learner’s mind.” Bruner elaborated on this perspective as follows:

In theorizing about the practice of education in the classroom (or any other setting for that matter), you had better take into account the folk theories that those engaged in teaching and learning already have. For any innovations that you, as “proper pedagogical theorist,” may wish to introduce will have to compete with, replace, or otherwise modify the folk theories that already guide both teachers and pupils.

(p. 46)

Notwithstanding its concern for teachers’ folk theories and its inclusion of teachers as participants in the inquiry process, research on teacher thought and action in context is limited in the view of teaching that it affords. For example, its bias toward typicality in descriptions of local knowledge tends to freeze actors in the “ethnographic present.” This makes envisioning difference, variation, or change difficult. Its reports tend to generalize within groups, leading to texts that can stereotype individuals and groups. Its descriptive language can reify limiting images of the teacher (as Caucasian, monolingual, and suburban, for example), the teacher’s work (as isolated or bounded in the classroom), or the teacher’s time and place (contemporary, suburban). Thus, although their research aims at descriptions of local knowledge in use, biases, methodological choices, and limitations in styles of research reporting can leave very little room for examination of difference or, ultimately, for consideration of praxis (Florio-Ruane, 2001; Ladson-Billings, 2000; Oakes & Lipton, 1999).

To redress some of these problems of theory, ideology, method, and representation, researchers have again widened the arc of light in research on teaching and teacher learning to include explication of local knowledge(s) in contact, conflict, and transformation. This is intertextual work, drawing on literature, literary criticism, political theory, history, and social analysis to examine difference, conflict, power, and change. In this light, research involves critical dialogue among various participants and stakeholders in the teaching and learning process, from parent to politician, novice teacher to policy maker, child to administrator. Attempting discursive research of this sort within an urban preservice teacher education setting, Morrell and Collatos (2001) applied critical theory to educational research, asserting that “true teacher learning and classroom transformations will not occur until teacher-students and student-teachers engage in critical and liberating dialogue where each group informs the other as both grow in consciousness and sensitivity” (p. 6). The view of teaching and research on teaching as dialogue stands to add yet more light to a field of research that has been centered on the teacher. It may decenter teaching, finding other ways to explore the complexity of the educational process. In addition, it identifies other centers for our gaze if we aim to understand the teacher’s work. For example, we need to know a good deal more about the experience of teaching from learners’ perspectives (Shultz & Cook-Sather, 2001) and also from the perspectives of the families and communities.
from which learners come (Moll & Greenberg, 1990) if we are to discover and understand new and perhaps more effective ways to serve students of and for the future. Doing this entails shifts in researchers’ points of view, admits of more voices and methods of inquiry, and teaches us anew about teaching and the education of teachers.

In this critical light, teaching is open to reconceptualization. Many tacitly held ideas about the role of the teacher, the nature of knowledge, and the purpose of education are called into question when teacher and learner come together in dialogue and where knowledge is not something to be produced in the student by means of teacher thought and action but is a joint construction, continuously negotiated and developed as a part of life in a learning community (see, e.g. Lave & Wenger, 1991).

WHAT WORKS? THE USE OF COMPLEXITY

Entertaining complexity is difficult under any circumstances and especially in situations of urgency. Although our problems in education are urgent, we must be cautious about the ways that urgency can limit inquiry and understanding. What works? is the question most often asked by practitioners and policy makers of our applied research on teaching and teacher education. Sometimes we can answer this question helpfully and wisely. Sometimes we do not answer it, choosing to reframe it. Sometimes information useful to practitioners and policy makers comes from research on questions they had not thought to ask or from modest, easily overlooked studies of ancillary or exploratory nature. Sometimes we bear down on a practical problem with all of our resources only to have it elude us within the limits of our theory and research design. At other times, serendipity leads the prepared mind to unanticipated findings that are of both theoretical importance and practical value.

Teacher education faces difficult problems as we begin the new century—recruiting a diverse teacher cohort, preparing teachers better to serve our pupil population, enriching our canon with accounts of teaching in diverse contexts, and improving our effectiveness to educate all children, especially those in poverty who are poorly served by public education. Yet if a climate of crisis prevails in the face of such problems, the public may look to research for authority, efficiency, and simplicity. Although the temptation to succumb to this seductive position may be strong, researchers need to remember that it is a misrepresentation of what we can provide, a distortion of our efforts to provide information that is useful and carefully expressed. To illustrate, I will make brief reference to two examples that may seem far afield from teaching and teacher education: research on cancer and research on literacy in Liberia, West Africa.

First, cancer. Recently I read an article in The New Yorker magazine. Although it critiqued the U.S. “war on cancer” of the late 20th century, it also spoke to a national tendency to choose the metaphor of war (with all the discipline and urgency it implies) to solve difficult social problems (e.g. the war on drugs, the war on poverty) (Groopman, 2000). This critique haunted me because of its applicability to our field. Using the 20-year war on cancer as his case example, Groopman (2000) reported that the coming together of serious problems, philanthropy, and political power led to the development of a federally funded program of research that aimed to hasten the finding of cures to cancer by means of particular lines of inquiry thought to be most relevant. Thus, research proposals funded in the war on cancer targeted with laser-like precision areas of inquiry thought to hold the answers to cancers of many kinds.

More than 20 years later, although there have been modest successes, we can hardly say that the war on cancer has been won. Perhaps the war was itself a casualty of its own narrowness of mind. By targeting cancer narrowly and perhaps selecting its targets with insufficient information, it became difficult to get funding for research that widened the arc of light on the complex of diseases we call cancer. And more troubling, some of the funded studies had prematurely closed
in on experimental treatments, sometimes with dire results to patients. Paradoxically, some of what researchers learned in the war on cancer did not help us cure cancer but helped us understand other difficult diseases outside the manifest scope of work (e.g. HIV). And finally, in a number of cases, research undertaken at the fringes of or entirely outside the cancer centers in the United States had unanticipated findings of use to cancer researchers (Groopman, 2000).

Now to Vai literacy. The late Sylvia Scribner (1984) was a pioneer not only in her commitment to scholarship addressing policy makers but also in her awareness of the need for critical, reflective action as an applied researcher. Her essay "Literacy in Three Metaphors" was addressed to policy makers in international development. Based on her research on the local meaning and use of literacy among the Vai in Liberia, Scribner combined methods drawn from anthropology and psychology to locate literacy in culture. Scribner’s vignettes of Vai literacy illustrate different ways people use written language. Taken this way, Scribner’s accounts offer only one limited and reproductive account to policy makers. Readers do not learn about their own thinking, or the frames of reference within which they are enmeshed. Implicitly, they think of teaching literacy as helping others not to become literate but to “become like me.”

Instead, however, Scribner (1984) used her research-based vignettes of Vai literacies as metaphors (literacy as a state of grace, as a functional tool, as power). Not every reader of the Vai accounts cares specifically about programs for literacy education in Liberia. But to the extent that readers care about what it means to presume to design, administer, or assess educational programs of any sort, they learn from the metaphors Scribner offered: that literacy is not a unitary practice and that it is intimately tied to context of use and also to history, politics, and culture. She used figurative language to link the reader not only to the expected declarative description of the “other” (what Margaret Mead would likely consider fulfilling the necessary objectivity of observation), but poetically to images of people using script in many ways and for many purposes (what Mead would identify as the empathy also required of good human science). This blend of mind and heart invites the reader to reflect on his or her own folk wisdom and local knowledge by asking, What does literacy mean in my life, time, and society? How do my tacitly held norms and values for its practice limit my thinking about other literacies? What responsibilities do I have, as a person empowered to make decisions affecting the literate lives of others, to be thoughtful about not only the limits of their knowledge but also the limits of my own? To the pragmatic question, What works? we can think of Scribner answering by means of her research, it depends on what you mean by literacy. And, by the way, defining literacy is not a simple, once-and-for-all act.

We can miss the point in applied research by focusing too tightly and prematurely on a problem or by misconstruing the nature of the problem. Describing research as the lens through which we view complex problems of our practice, Purcell-Gates (2000) offered us four rigorous lenses, each useful in different ways in educational research: experimental, correlational, descriptive, and ethnographic. Noting the strengths and limitations of these approaches, she made a strong case for multiple views of complexity that deserve to be used in concert rather than in competition to enhance our understanding of literacy teaching and learning. She pointed out that many educational issues and problems clearly require research that draws on multiple perspectives, approaches, and procedures . . . To restrict educational research to one or two paradigms . . . would unacceptably restrict our ability to address the complex challenges of educating all learners in this complex, multicultural society of ours to their full potential.

(p. 4)

In many ways, that is the legacy of research on teaching and teacher education in the 20th century.

It is a paradoxical feature of social interaction that in times of stress or urgency, we are apt to limit the light on the subject rather than to open up possible avenues of exploration. In
contemporary times, we are not only metaphorically at war with complex social and educational problems but functionally at war (though at this writing not formally declared), not with a bounded nation-state but with a complex, indeterminate collective of terrorists. In response to the urgency of our situation, we have made many moves toward focus and hierarchical order. Yet curiously, out in the desert, where the enemy is not marching in flanks but hiding in caves, we have had to rely on small, stealthy, and nonhierarchical groups to locate intelligence by which we can direct our forces. Perhaps this is one reason the war on terrorism seems strangely new to our senses and sensibilities.

In a classic essay on the concept of role, Goffman (1961) described the idea of “role distance” or the different ways a formal role is enacted in different situations. He noted that whereas there are many ways to behave in enacting a formal role, these tend to move closer to the role’s putative definition when crisis or urgency is perceived. Thus, the surgeon may joke and banter with scrub nurses and interns prior to the incision but utter only clipped, highly compact imperatives (“Clamp.” “Scalpel.”) as the patient’s entrails are exposed. Bernstein (1975) similarly argued that the work of people can be more flexibly and horizontally organized in situations of low stress. However, when resources are limited or there is external pressure, organizations tend to work in more specialized, hierarchical ways. To the extent that formality, what Frake (n.d.) called “the black tie of scholarship,” is highly valued, these moves serve to confer a sense of efficiency, quality, even virtue, to particular genres of research, ironically at the very moment when it would seem that a wide and varied exploration is needed most. The moves toward discipline, formality, and hierarchy are, by definition, moves that stratify. They are moves that mute or eliminate some voices and exaggerate the power of others. In this way, paradoxically, the calling of a crisis can lead to the exclusion of the perspectives and voices of people closest to the problem under study—or at least those most directly implicated in the solutions proffered by research.

**IN CONCLUSION: KEEPING IT COMPLEX**

Each new venture in research is neither a sign of progress toward some Aristotelian truth nor a stop on the way to a wished-for grand synthesis. However, studies of the messiness of practice are not de facto messy studies. As applied researchers in the human sciences, we work to illuminate teaching and teacher education in an ongoing way and by means of sustained, expansive, responsive, critical, and multivoiced scholarship. Yet this process seems paradoxical in the present moment, when our field is under great pressure from our various publics and a political rhetoric of crisis permeates discussion of teaching, teacher education, and teacher quality. Researchers, at times, seem to be proceeding at too leisurely a pace. We sometimes fail to synthesize our work and apply what we have learned to problems of practice. Yet our deliberative pace and care with respect to truth claims are not efforts to dodge the responsibility of an applied field. They are part and parcel of our discipline, forcing us to slow down sufficiently to be sure that we balance what Margaret Mead (1976) took to be the dual commitments of practitioners of a human science—empathy and objectivity.

In addition to studies supported or contracted for by powerful agencies and benefactors, we need, as a field, inquiry into the very nature of the crises to which we are asked to respond as well as consideration of those interests and problems left outside such a scope of work. In short, we need thoughtful dialogue about the ways that teaching and teacher education problems are identified, understood, queried, and helpfully addressed by our research. By means of this dialogue, we may continue to grow our field and its potential not only to solve practical problems but also to create new knowledge and to entertain problems as yet undiscovered. Unless we take the time and the responsibility to keep our work—and our field—complex, we will be unable to resist
crisis-driven, regressive behaviors that harden the lines of power and authority and limit educational inquiry. Unless we keep teaching and teacher education complex, we will fall prey to some or all of the following: pitting approaches to research against one another in the name of rigor; privileging natural science-based approaches solely because of their compatibility with the language and assumptions of policy; failing to recognize that all approaches to research have limited purview; and disregarding insights from critical, alternative approaches that seek to increase the light in our studies of teaching and teacher education.

ACKNOWLEDGMENT

I thank P. David Pearson, with whom I have been privileged to teach a seminar on language, literacy, and learning, for helping me to think about the topic of this article.

8.3 Knowing teaching

The intersection of research on teaching and qualitative research

Magdalene Lampert
University of Michigan, Ann Arbor

In this article, Magdalene Lampert argues that teachers can be both initiators and active participants in a research agenda, adding valuable insider knowledge. She considers three points: “the potential for teacher research to change ideas about who is responsible for producing professional knowledge, the benefits and dangers of inserting the self into social science, and the challenges of presenting the problems of a practice from inside that practice.”

Educational researchers struggle incessantly with the relationship between knowledge and action. What does it mean to do scholarship in an applied field? What methodologies are appropriate to capture the problems of the field? Are these practitioners’ problems? Are they problems worthy of scholarly inquiry? What is the relevance of the findings of scholarly research for improving practice? In wrestling with these questions, educational research and qualitative research have intertwined and influenced one another, raising issues that mix content questions with methodological problems. In the halls of academe, questions about voice, about the relationship between the researcher and the researched, and about the relevance of scholarship to the solution of social problems have always been high on the agendas of both qualitative research and educational research. In the corners where educational research attends to teaching, these questions have been particularly prominent.

WHAT IS RESEARCH ON TEACHING?

I started teaching in the 1960s, inspired by contemporary commentaries about what was wrong with schools. Among the most influential of these commentaries were stories about teaching written in the first person by reformers who taught school to find out what was going on there and what could be done about it.1 My experience as a teacher in an urban high school confirmed what I had been reading. But, when I turned from classroom teaching to the academic study of teaching in 1978, I discovered that books like these were not found on the assigned reading lists in my graduate school courses. Only in a history seminar did I encounter some writing about practice by teachers from the 1920s and 1930s, teachers who started schools, designed curricula, and studied children.2 In the contemporary writing about teaching that I was assigned, the teacher’s voice was not to be heard.

I am not the only one who has been puzzling about the teacher’s role in research on teaching. In *Educational Researcher*, the monthly journal of the American Educational Research Association (AERA), the question of who in my research community speaks appropriately of teaching
and how they should go about studying practice has been raised repeatedly over the last decade. Most recently, Gary Anderson and Kathryn Herr examined the problem of making room for “rigorous practitioner knowledge” in schools and universities. They pointed to the classic relationship between professional knowledge and “systematic knowledge produced by schools of higher learning” as one of the sticking points in defining appropriate methods of research on teaching, as well as in determining who is qualified to do it. As scholars argue about both the purposes and the validity of research on teaching, the question of who should do research on teaching spills over into questions about method and mixes with assertions about appropriate genres for reporting research. Is research on teaching a scholarly effort to understand a complex practice? Is it only of interest if applying it produces student learning? Is it an instrumental project, identifying problems, proposing solutions, and testing them in practice? Is it meant to produce knowledge for teachers? Or for those who prepare teachers? Or for those who control teachers’ working conditions?

In the midst of all these questions, not only paradigms but also products and venues for communicating findings have proliferated. The AERA established a new division (Division K) for research on “Teaching and Teacher Education” in June 1984. It quickly became the largest division in the association, with seven different sections. From a practitioner’s perspective, the boundaries among the sections are somewhat puzzling: one deals with research on teaching “subject matter,” one with research on “collaborative or partnership settings” for teaching, one with research on teaching in multicultural settings, and one with research on “teaching and learning in the contexts of teachers’ work,” which is further divided into a subsection for pedagogical aspects and a subsection for organizational aspects. A separate section is devoted to “self-study and practitioner inquiry and scholarship on teachers and teaching.” In all of the sections of Division K, research is “construed broadly to include but not be limited to, philosophical, historical, ecological, ethnographic, descriptive, correlational, or experimental studies.” Research on teaching and qualitative research have grown and developed together, and the hodgepodge that has resulted from their interaction has become an institution.

TEACHER RESEARCH

One element in this jumble of practice-focused inquiry stands out as especially worthy of commentary. The formal addition of practitioners to the community of researchers on teaching, indicated by their inclusion in the AERA as well as other scholarly institutions, seems to raise the most interesting questions for qualitative research. The shift from thinking of research as something that is done on teachers to a kind of work that is done by teachers could not have happened without the concurrent growth in appreciation of the contributions of qualitative research to the field of educational scholarship in recent years. In the 1970s, qualitative research helped to open educational research to questions of meaning, perspective, ownership, and purpose, and into this opening came teacher research.

Teachers have become participants in academic communities of research in several different ways. Some who make their living by teaching full time K-12 schools conduct inquiry in their own and in one another’s classrooms. Others collaborate with university researchers while retaining their teaching positions, contributing the perspective of daily practice to the questions under study. In a few cases, teachers regard inquiry to be part of their day-to-day work in classrooms. In other cases, it is one among many opportunities for “professional development,” offered alongside summer institutes on subject matter, workshops on classroom management techniques, and conference sessions on new curricula. And then there are faculty members of colleges and universities who choose to teach in K-12 schools as a means to create a site for pursuing investigations of practice. Some teach part of every day, others teach full time for a year or more.
A multitude of books and articles are produced by this conglomeration of practitioners, some published in academic presses and journals, some in popular media. A few hybrid presses and journals have emerged that would be hard to identify as one or the other, and which count a majority of teachers among their authors. Conferences are devoted to teacher research, and funding agencies are making money available to support it. The genres used to convey the findings of teacher research are as varied as the ways in which this work is structured.

**ISSUES RAISED FOR QUALITATIVE RESEARCH BY TEACHER RESEARCH**

Teacher research raises numerous issues for scholars who do qualitative research. Here I will consider only three: the potential for teacher research to change ideas about who is responsible for producing professional knowledge, the benefits and dangers of inserting the self into social science, and the challenges of presenting the problems of a practice from inside that practice.

**Professional responsibility**

If teachers are doing research on their own practice, might they assume a central role in professional knowledge production? If teaching problems were considered to be the responsibility of the profession, rather than private trials for individuals to endure or mechanical defects for outsiders to repair, a great deal of expertise could be mustered in the service of improving practice. Such a move would redefine power relationships between practitioners and researchers, and raise questions about what nonpractitioners have to add to the “knowledge base.” Practitioners doing research on practice could change the kinds of questions that are asked and the new understanding that is produced. If teachers write about their work from the inside, including both personal and professional perspectives on the problems of practice, their work could substantially alter what we now think of as appropriate conventions in the discourse of applied research. As they communicated about their inquiry, teachers would develop a new syntax and a new semantics to add to those of the academic disciplines in the study of educational phenomena. Just as sociologists, anthropologists, and psychologists now both use and modify a variety of qualitative methods, practitioners would test and contribute to the development of these approaches to producing new knowledge.

Although appealing, looked at through an outsider’s lens, this scenario is not without its problems. One of them has to do with where we draw the line between research and thoughtful practice. As Ken Zeichner has asked, “Is it proper to call it research when teachers examine their practice in a systematic and intentional manner?” I will not take on that issue here, as Zeichner has already done so, and he is more qualified to give it adequate treatment than I. Another problem has to do with the social arrangements around teaching that tend to stifle inquiry. Creating a professional discourse in teaching has been a persistent challenge in the United States. In 1975, Dan Lortie wrote:

> The preparation of teachers does not seem to result in the analytic turn of mind one finds in other occupations whose members are trained in colleges and universities . . . One hears little mention of the disciplines of observation, comparison, rules of inference, sampling, testing hypotheses through treatment and so forth. Scientific modes of reasoning and pedagogical practice seem compartmentalized; I observed this even among science teachers. This intellectual segregation puzzles me; those in other kinds of “people work” (e.g. clinical psychology, psychiatry, social work) seem more inclined to connect clinical issues with scientific modes of thought. This separation is relevant because it militates against the
development of an effective technical culture and because its absence means that conserva-
tive doctrines receive less factual challenge; each teacher is encouraged to have a personal
version of teaching truth.12

In the past twenty-five years, many questions have been raised about the value and character of
“the scientific method.” But the problem that Lortie calls “intellectual segregation” persists among
teachers, as does the rarity of observation, comparison, rules of inference, sampling, and testing
hypotheses through treatment.13 What Lortie calls “a personal version of teaching truth” con-
tinues to exist for most teachers alongside of and often untouched by the “teaching truths” that
are produced by university researchers.14 No professional language for describing and analyzing
practice has developed in the United States, even as teachers reject the descriptions and analys-
es of scholars.15 This deficit is particularly alarming when it is considered in light of recent
psychological and linguistic work on the relationships between shared language, the develop-
ment of understanding, and problem-solving activity.16 It is notable that teacher educators are not
drawn from the ranks of accomplished teachers and that “practice teaching” is rarely conducted
as the kind of apprenticeship that doctors and lawyers experience as they work on practical
problems together with more experienced members of their intended profession. What this
means is that the language of practice remains flat or nonexistent.

That teachers do not learn simply by engaging in collaborative professional inquiry has
as much to do with the structure of their work as it does with a disposition toward privacy and
intuition. Currently, few teachers in the United States have the time and space in their work lives
to think about the dynamics of teaching, let alone the resources to document their work and study
the problems of their practice. Collaborations among practitioners to work on the problems of
practice are considered “luxuries,” rather than essential components of the work, as they would
be in other professions such as medical or legal practice.17 In Japan, by contrast, the structure of
professional development in teaching is built on the assumption that teaching is a collaborative
process rather than a private enterprise, and that it is improved through teachers’ collaborative
inquiry, including peer planning of curriculum and instruction.18 In K-12 classrooms, Japanese
teachers regularly teach “research lessons” to their students that are designed, recorded, and
discussed by groups of practitioners working together on a particular problem of curriculum and
instruction. Such work—which occurs at the school and district level as well as in national profes-
ional organizations—is thought not only to improve classroom practice, but also to connect
classroom practice to broader educational goals and to explore conflicting ideas. Similarly, in
China, a decades-long tradition and a well-articulated structure has new and experienced
teachers collaborating in inquiry and practical problem-solving.19 In the United Kingdom, a strong
tradition of “action research” by teachers began in the 1960s and continues today.20 The teachers
who produce and communicate knowledge of teaching in these cultures are not a special brand
of “teacher researchers,” they do what they do as part of their everyday practice, accepting the
study of teaching and the solving of its problems as a professional responsibility.

Although the structural supports for it are still weak, teacher research on practice seems to be
gaining ground. As teachers talk at conferences and write for their peers, they are beginning to
create a genre of professional inquiry. As scholars who teach make their teaching experiments
available for common investigation, they develop a shared text for analysis by others and a
language of conceptual frames based in practice. This work is part of a modest but growing set of
complementary institutional efforts, including teachers’ collaborative assessment of student
work, district-level teacher research groups, professional development schools, and the presen-
tation of practice for assessment by fellow teachers in teacher portfolios, all of which might qualify
as forms of “qualitative research.” As these new professional venues become opportunities for
teachers to conduct inquiry and communicate their findings, how will their work be regarded in
relation to the larger picture of “knowledge production”? Should practitioners’ research meet the
same standards of method as scholarly research? If they invent their own methods, will these methods make their way into academic discourse? Should they?

**Bringing the self into scholarly activity**

Writing academic texts in the first person is a current trend in many of the social sciences. Teacher research is but one small example of this phenomenon, but it gives qualitative researchers in education a context in which to examine the potential and the problems of this kind of writing. There are at least three issues of interest to qualitative researchers that arise from getting the self into a central position in research on teaching: the potential and pitfalls of autobiographical narrative as a scholarly genre; the capacity to uncover invisible, relational aspects of the work that have not been recognized by outsiders; and the mixture of responsibility and analysis that such work entails. In 1985, as a justification for writing about my teaching in the first person as a form of scholarship, I argued:

> Who the teacher is has a great deal to do with both the way she defines problems and what can and will be done about them. The academician solves problems that are recognized in some universal way as being important, whereas a teacher’s problems arise because the state of affairs in the classroom is not what she wants it to be. Thus, practical problems, in contrast to theoretical ones, involve someone’s wish for a change and the will to make it. Even though the teacher may be influenced by many powerful sources outside herself, the responsibility to act lies within. Like the researcher and the theoretician, she identifies problems and imagines solutions to them, but her job involves the additional personal burden of doing something about these problems in the classroom and living with the consequences of her actions over time. Thus, by way of acknowledging this deeply personal dimension of teaching practice, I have chosen not only to present the particular details of [other] teachers’ problems, but to draw one of these problems from my own experience.21

In the 1980s, research on teacher thinking expanded to include the teacher’s voice alongside the researcher’s, as scholars sought to understand why practitioners act the way they do. In naming the teacher thinking that this approach revealed as “practical knowledge,” researchers like Freema Elbaz, Jean Clandinin, and Michael Connelly raised new epistemological questions, as well as new questions about what sorts of research methods were appropriate for the study of teaching.

Another way to bring teachers’ voices into the research literature has occurred through the publication of autobiographical narratives, but several scholars have advised proceeding cautiously with this approach. In a keynote address to the International Study Association on Teacher Thinking in 1995, Ivor Goodson observed that it was dangerous to believe “that merely by allowing people to ‘narrate’ that we in any serious way give them voice and agency.”22 Goodson quotes Cynthia Chamber’s review of Connelly and Clandinin’s book, *Teachers as Curriculum Planners: Narratives of Experience*:

> These authors offer us the naive hope that if teachers learn “to tell and understand their own story” they will be returned to their rightful place at the center of curriculum planning and reform. And yet, their method leaves each teacher a “blackbird singing in the dead of night”; isolated, and sadly ignorant of how his/her song is part of a much larger singing of the world.23

He notes as well that Kathy Carter celebrated the insertion of teachers’ voices into educational research in 1993, but she also observed:
For those of us telling stories in our work, we will not serve the community well if we sanctify story-telling work and build an epistemology on it to the point that we simply substitute one paradigmatic domination for another without challenging the domination itself. We must, then, become much more self-conscious than we have been in the past about the issues involved in narrative and story, such as interpretation, authenticity, normative value, and what our purposes are for telling stories in the first place.\textsuperscript{24}

Working in the fields of psychology and sociology, Louise Kidder and Michelle Fine have made similar critical comments about the celebration of the insider's narrative. They assert that it is the responsibility of researchers who stand outside the context of practice to “assert interpretive authority,” placing the actor’s story in relation to other actors and the world of ideas. Citing Joyce Ladner’s commentaries on race research, they observe, “For Ladner, the very point of conducting social research is to interrupt the ‘common sense’ frames, ideologically driven by social arrangements or what she calls ‘the system,’ and to provide alternative lenses for viewing social behavior.”\textsuperscript{25} Kidder and Fine suggest that multiple lenses of this sort are possible and desirable in researchers’ interpretations of practitioners’ stories: they call this work “kaleidoscopic.”

How we regard the personal in teacher research is both a practical and a deeply epistemological question, forcing us back to the enduring puzzles educational researchers deal with about how to relate what is learned from a single “case” in all its complexity to other situations in which similar problems arise. What does it mean for problems that arise for particular people in particular contexts to be similar across settings? What additional skill or knowledge does a practitioner, or for that matter a scholar, need to have to take knowledge from one case into another?

Problem of representation

Once you know teaching from the inside, how do you communicate what you know so that there can be an accumulation of knowledge in the field? Writing about first-person teacher research in mathematics education, Deborah Ball goes beyond the importance of inserting the teacher’s voice into the discourse of teaching and raises questions about the nature of autobiographical argument: on what basis are claims made by first-person writers, and on what evidence do readers accept them? Ball observes that teachers writing about teaching force us to ask what we mean by “truth” and to examine the writer’s purposes as we define it. She draws on Ruth Behar’s work, which describes the changing discourse of anthropology to emphasize that autobiographical scholarly writing is more difficult than more familiar academic argument. Behar issues a caution to which all who are involved in such projects would be wise to attend:

As is the case with any intellectual trend, some experiments work out better than others. It is far from easy to locate oneself in one’s own text. Writing vulnerably takes as much skill, nuance, and willingness to follow through on the ramifications of a complicated idea as writing invulnerably and distantly. I would say it takes greater skill.\textsuperscript{26}

Why would the teacher researcher be “writing vulnerably”? What is it about this kind of writing that requires so much skill, given that it is the telling of one’s own story? As a teacher writing about my own teaching, I certainly have access to special knowledge, but at the same time, I am constrained by the limitations of any medium to express the multiple aspects of what I know. Although it is my aim to retain the richness and complexity of what is going on in what I write about my teaching, being in the middle of it makes me painfully aware of the impossibility of telling the whole story. Language, even supplemented by other media, is simply inadequate to capture my experience and knowledge of teaching practice. It is inadequate even to capture all of the aspects of an event, to say nothing of representing the constellations of feelings and
intentions imbedded in that event. That I can have more of a sense of the whole of what is going on than any observer is both a blessing and a curse when I try to write about it.

Practice is doing. As I have argued, the study of practice thus begins in the setting in which a particular practitioner acts. To study practice means that I cannot succeed by limiting the focus of my inquiry, since a limited focus hinders practical problem-solving. Yet, in the course of attempting to tell about any practice, even if the telling is in the first person, one necessarily formalizes what has been learned, leaving out some aspects of the experience highlighting others. It is not only the outsider who can bring what Kidder and Fine call "kaleidoscopic interpretations." For any inquiry into one’s own practice, there are many possible stories to tell. For every story that is told, there are many possible meanings to interpret. Stories about practice are mirrors of experience: like all texts, they are constructed by the author with certain intentions in mind.27 When one is writing about oneself, no description seems adequate to the experience, and yet without description, what is learned remains private and unexamined.

This judgment about the inadequacy of language to represent my multi-faceted experience of practice is more than scrupulous self-criticism. My audience can hold me to a higher standard of verisimilitude than they would other authors of case studies of teaching because I am the teacher I am portraying. Other kinds of writers about teaching are excused for leaving out considerations of gender or political context or parental relations or subject matter because these are outside of their area of expertise. As a teacher I cannot ignore any of these domains, and I am also expected not to ignore them as a self-referential writer. In 1987, I turned to video as a possible solution to the problem of representing the complex nature of my teaching to others. I reasoned that, with video, the viewer would have greater access to the complex interactions occurring in the classroom even if they were limited by my editorial selection of a few minutes of the lesson from a longer stream of activity or by the angle of the videographer’s lens. Such representations of the practices of teaching and studying seem authentic because what is going on for the participants seems to be available to the viewer all at once, rather than filtered through the interests of a describer.28 In contrast to writing, video makes it possible to have a running image of the teacher–student–subject interaction without isolating these into single elements that need to be put back together in some way to convey the whole.

When I show a videotape of my classroom, the question of how much “background” I need to provide and what to tell people before showing the tape always worries me. I am never satisfied that I have figured it out. Invariably, I run up against the frustration of wanting to show and say more than I have time for, and wish I could say, “You had to have been there to understand what that was about.” Once viewers start to comment on what they see me doing on the tape, the video seems to represent so little of what I know about what is going on. And what I know from “being there” has a lot to do with reasoning about the actions we are seeing on the tape. Speculating about why I did what I did and evidence of the reasonableness of those actions would need to be grounded in much more information than what was available. The possibility of real-time representations of teaching on video seems to exacerbate the problem of communicating about my practice rather than solving it.

My experiences with video pushed me to want to invent a better representation of teaching practice to serve as a basis for collaborative analysis and problem-solving. Working as elementary teachers, teacher educators, and researchers on teaching, Deborah Ball and I began to experiment in 1989 with multimedia. We assembled multiple records of our practice in an electronically accessible database that could be used by a teacher and her audience as the text to be interpreted in analytic discussions about practice. Although the promise of the technology has been greater than the reality, this representation of teaching continues to be both practically and conceptually appealing.29 Multimedia technology has the potential to enable us to represent the kind of knowing that Ball and I find essential to our own teaching but lacking in research on teaching—what Lee Shulman has called “strategic” modes of knowing in practice.30 Shulman’s
characterization of strategic knowing is strikingly similar to the rhetoric used by developers of multimedia technologies. He observes that propositional knowledge is what is most conventionally delivered in academic settings to be “applied” in practice. He claims that case knowledge, with its vivid detail, makes the propositions it illustrates more memorable, but is still clearly distinguishable from strategic knowledge—knowledge as it is used in actual situations of practice:

Both propositions and cases share the burden of unilaterality, the deficiency of turning the reader or user toward a single, particular rule or practical way of seeing. Strategic knowledge comes into play as the teacher confronts particular situations or problems, whether theoretical, practical, or moral, where principles collide and no simple solution is possible. Strategic knowledge is developed when the lessons of single principles contradict one another, or the precedents of particular cases are incompatible.

It is precisely this sort of representation of practices of teaching that multimedia is supposed to make possible. It appealed to us because it could capture the complexity of practice that we saw from the inside, the strategic piece that required both thinking and doing but did not have a simple face. And perhaps it is this desire to understand the strategies teachers use in practice that drives the development of teacher research more broadly.

**WHERE NEXT?**

In 1990, the research team that I was working with conjured up the idea of a computer supported database called the “Investigator’s Working Environment” (IWE), which would further the study of teaching by enabling the activities of browsing, organizing, annotating, and displaying records of classroom teaching and learning in multiple media, along with individual and group commentaries on these records. The IWE was to be designed so that classroom practitioners and educational researchers, as well as students, parents, school administrators, and policymakers, could have access to the same set of records and add their interpretations to those records for access by others in both synchronous and asynchronous conversations about the problems of teaching. In 1999, we are closer to the IWE becoming a reality than we were ten years ago, and perhaps it represents an idea of where qualitative research on teaching might be going. New technologies for recording and archiving video and audio data and increasingly sophisticated communications and database technologies have great promise for integrating broad sweeps with deep analyses. Decreased financial and cognitive costs of access means that communication between scholars and practitioners can be more readily established on a common base of information. Electronic communications enable participation in conversations about a common text among participants that are not limited by time and place. And new database technologies make possible links between primary sources and interpretations of those sources, opening up new ground on the old questions of how “results” of research are to be reported and their validity judged.

What research on teaching has become, particularly in the hands of teacher researchers, opens up new prospects and new puzzles for qualitative research. The new tools that practitioners and researchers have at their disposal will change both what kind of data can be collected and how analyses of that data can be carried out and communicated. As qualitative research on teaching evolves, practitioners and researchers will need to take account of the contributions of teachers who take on the responsibility of using these tools as a basis for generating context-specific professional knowledge. Practitioners and researchers will need to consider what counts as a “good” interpretation of events as the stories of practitioners about those events are placed
alongside interpretive scholarship of various sorts. And practitioners and researchers will need to face the representational challenges of communicating about practice when it has been “known” from the inside. As we allow more voices into the conversation and enable the juxtaposition of their analyses, we will struggle with understanding the nature of practice, the nature of knowledge, and what knowledge is good for.

NOTES

2 _The Dewey School_, written by teachers at Chicago Lab School (Katherine Camp Mahew and Anna Camp Edwards [New York: Appleton-Century, 1936]), is a particularly interesting example of this genre.

9 For example, “Voices from the Classroom,” sponsored by The Center for Research on Evaluation, Standards and Student Testing (CRESS), Davis, CA; the teacher research section of the Ethnography Forum, University of Pennsylvania; The International Conference on Teacher Research, held annually by the National Writing Project; The Spencer Foundation; National Council for Teacher Education (NCTE).

15 The potential of National Board for Professional Teaching Standards (NBPTS), Interstate New Teachers Assessment and Support Consortium (INTASC), and National Council for the Accreditation of Teacher Education (NCATE) to support this development are described in *What Matters Most: Teaching for America’s Future* (New York: National Commission on Teaching and America’s Future, 1996). For a discussion of the difference and relationship between local and professional language, see Donald Freeman, “Renaming Experience/Reconstructing Practice: Developing New Understandings of Teaching,” *Teaching and Teacher Education*, 9 (1993), 485–497.

21 I refer to “How Do Teachers Manage to Teach?” *Harvard Educational Review*, 55 (1985), 180; see also footnotes to this article and its brief review of supporting literature.

29 For a full description of this project and references to similar projects, see Magdalene Lampert and Deborah Ball, *Teaching, Multimedia and Mathematics: Investigations of Real Practice* (New York: Teachers College Press, 1998).
31 See, for example, the essays in Sueann Ambron and Kristina Hooper, Interactive Multimedia: Visions of Multimedia for Developers, Educators, and Information Providers (Redmond, WA: Microsoft Press, 1988).
Part 8
Commentaries
Toward a better understanding of teaching and learning about teaching

*John Loughran*
Monash University

Because a teacher works with many students within emergent, normative, and negotiated settings, his or her knowledge is not simply instantiated in patterns of observed behaviour, nor is it simply invisibly scripted and in the head. . . . Teachers retain sufficient agency to act in new, creative ways. As such, teaching is both ordered and responsive to norms and standards and also improvisational and responsive to other participants.

(Florio-Ruane, 2002, pp. 209–210)

As Florio-Ruane (above) makes abundantly clear, teaching is multifaceted. Yet paradoxically, although a recognition of the skills, competencies and knowledge that are enmeshed in practice may be helpful for looking into that which teaching comprises, simply reducing it to individual elements only serves to detract from an appreciation of its underlying complexity. A teacher’s ability to improvise, adapt and respond in different ways to different pedagogical situations offers insight into the creativity, necessary professional autonomy and expertise inherent in quality practice, while simultaneously highlighting its somewhat ethereal nature. Clearly, as teaching is so complex it stands to reason that it must be difficult to capture, analyse and portray.

Teacher education then, in its attempt to mediate both teaching and learning about teaching must explicitly grapple with the complexity of practice while at the same time being sensitive to the fact that teaching is largely tacit by nature (Polanyi, 1962). In light of this, it is little wonder that teaching about teaching is often so poorly understood and misrepresented (both within and outside of the profession). Therefore, as a consequence of this situation, it is important that teacher educators are responsive to critique (rather than ignoring or naively accommodating it) in order to ensure that the work of teacher education is better understood.

Criticism of teacher education has been a recurrent theme for many years. Sadly, part of the implicit criticism of teacher education is linked to the taken for granted nature of teaching (and by extension, teacher education) which reinforces the notion of teaching as an undervalued profession. But as the introduction to this chapter suggests, this situation may itself be exacerbated by a lack of understanding of all that teaching and teacher education really involves. For example, Gage (1978) stated that “the importance of teacher education is commensurate with the importance of teaching” (p. 42) and he drew on Ryle’s (1949) distinction between “knowing that” and “knowing how” as one way of interrogating teacher education practices in order to illustrate that “knowing about” teaching and “doing teaching” are not necessarily one and the same.

In many ways, Gage’s argument reflects long held concerns for teaching and teacher education dating back to the work of Dewey in the Chicago Laboratory School: “. . . Dewey (1938) drew attention to the need for experience to be seen as a shaping force in
the development of thoughtful and alert students of education as opposed to an entrée
to a rudimentary proficiency in teaching” (Loughran, 2006, p. 22). Unfortunately, the
distinction between technical proficiency and professional practice has largely served to
establish arguments about teacher education based on a dichotomy rather than exploring
the problematic nature of teaching; something that is compounded when considering
teaching about teaching.

If teaching is viewed as problematic, then things that are viewed as absolute through
the dichotomous approach noted above such as: developing the best way of responding
to a given teaching and learning situation; creating the right curriculum for teacher
education; choosing the ideal candidates for teaching; or, constructing the model of
teacher education, are able to be translated into possibilities for enhancing understand-
ings for practice (as opposed to measures of practice), thus leading to more meaningful
and responsive approaches to teaching and learning about teaching. Perhaps one reason
why conceptualizing teacher education at the (constantly) varying points along a con-
tinuum is so difficult is related to the intricacies of genuinely responding to the reality of
learning; and all that that entails for teaching.

Myers (2002) has argued that teacher education has long been dominated by a “telling,
showing, and guided approach” to practice. This phrase captures how teacher education
practices are played out when the dilemmas and tensions borne of the complexity of
teaching about teaching are glossed over by inappropriately conceptualizing quality
teaching as “better telling.” Indeed, the use of telling, showing and guided practice is based
on an assumption that learning is simple and uncomplicated and that the knowledge and
experiences of teacher educators can be transplanted into students of teaching. It is
through such superficial views of the relationship between teaching and learning that
much of the critique (both founded and unfounded) of the work of teacher education is
based. Thus there is a pressing need for teacher education to respond more fully to the
implications inherent in better understanding the interplay between teaching and learning.
A considered response is crucial which means a serious focus on pedagogy is essential.

UNDERSTANDING PEDAGOGY

The use of the term pedagogy in countries such as the United Kingdom, United States,
Australia and New Zealand is often as a synonym for teaching. However, drawing on the
long tradition of pedagogy in Europe, it more readily “describes the relational values,
the personal engagement, [and] the pedagogical climate . . . [It involves] problematizing
the conditions appropriate [to] educational practices and aims to provide a knowledge
base for professionals in their work with children [students]” (van Manen, 1999, p. 14).
Teacher education obviously goes to the heart of the study of pedagogy. Teacher educa-
tion therefore must be, by definition, at the cutting edge of understandings of pedagogy
as it attempts to make clear for students of teaching the value of the how, what and why
of teaching for understanding. Inevitably then, teacher education must purposefully
embed learning about the complexity of teaching within experiences of its problematic
nature so that pedagogy itself is the central focus for both teachers and students of
teaching; and this should be reflected in the manner in which learning about teaching is
constructed.

Lampert (2000) illustrates this very point through her explanation of what it means to
her to be a teacher researcher. By paying attention to the opportunities for enhancing
professional responsibility, introducing the self into scholarly activities and addressing
problems associated with representing the complexity of practice she focuses attention on
the importance of studying practice from the inside. In so doing, she highlights how a teacher’s perspective on practice creates the “capacity to uncover invisible, relational aspects of the work that have not been recognized by outsiders; and the mixture of responsibility and analysis that such work entails” (p. 91). As a teacher researcher and concurrently being a teacher educator, Lampert works within the crucible of teaching and learning thus privileging her access to, and understanding of, pedagogy in ways that observers of teaching cannot. As she teaches her students and researches the influence of learning on teaching and teaching on learning, she develops new ways of seeing into the world of pedagogy. She is able to frame and reframe (Schön, 1983) situations, to create new and different vantage points and, in so doing, develop much deeper understandings of the complex relationship between teaching and learning.

Lampert’s work appears to be driven by concerns for practice similar to those involved in self-study of teaching and teacher education practices (Hamilton, 1998). Self-study is a field that opens up the complex world of teaching and learning about teaching in ways that can only be done by those who are participants in the work of teacher education. Hence, self-study offers a fresh way of responding to the dichotomous views of teacher education practices that have persisted for so long by presenting “an approach to researching practice that has facilitated the development of more informed understanding of teacher educators’ practice” (Berry, 2004a, p. 149).

In her extensive inquiry through self-study into her developing understanding of the demands associated with being a teacher educator, Berry (2004b) uncovered and described a number of tensions salient to learning about practice for teacher educators when they:

... attempt to match their goals for their students’ learning with the needs and concerns that student teachers express for their own learning. These at times conflicting purposes are part of the ever-present ambiguity of teachers’ (and teacher educators’) work and are, as Lampert (1985, p. 194) observes, “more manageable than solveable.”

(Berry, 2004b, p. 1313)

Berry goes on to list in detail six tensions that she describes as crucial to shaping her teacher education practices that, together, illustrate some of the wisdom and expertise inherent in creating teaching situations through which to explore with students of teaching both “knowing that” and “knowing how.” Her tensions are those of: Telling and Growth; Confidence and Uncertainty; Working with and Against; Discomfort and Challenge; Acknowledging and Building upon Experience; and, Planning and Being Responsive. Through these tensions, Berry captures the essence of that which teacher educators experience when confronted by the juxtaposition of simplistic and complex conceptualizations of teaching and learning about teaching.

In recognizing and responding to these tensions, contradictions and uncertainties of practice, pedagogical expertise becomes immediately apparent. However, managing this situation is not something that can be easily taught. It is difficult work and involves creating situations that must be experienced from both a teacher’s and a student’s perspective if it is to be fully apprehended and genuinely valued. Herein lies the challenge in teaching about teaching. There is a constant need for pedagogy to be a site for inquiry and growth. Clearly, both teaching and learning influence one another and, just as a teacher needs to be a learner so too a learner needs to be a teacher. Investigating and seeking to better understand the reciprocity necessary in this complex relationship is what makes it so difficult to accept that teacher education practices can (or should) be
simply codified. But that does not mean that teacher education practices should not be well articulated. In fact, articulating teacher education practices matters and is central to that which has been described as a pedagogy of teacher education (Korthagen et al., 2001).

**PEDAGOGY OF TEACHER EDUCATION**

In teaching and learning about teaching, the content, or subject matter, comprises at least the “theoretical” aspects of the “knowledge” of teaching (some might describe it as the *discipline of teaching*). Typically, much of this subject matter is distilled and offered through some form of curriculum . . . and is what Russell (1997) has described as the *content turn* in teacher education. However, an issue that is often easily overlooked in teaching and learning about teaching is the concurrent need to also pay careful attention to the practices employed in presenting the subject matter—the *pedagogical turn* (Russell, 1997). Hence, for both the teacher and the student of teaching, ongoing and conflicting roles continually complicate the competing agendas of *teaching and learning* about teaching. Not only must both teachers and students of teaching pay careful attention to the subject matter being taught, they must also simultaneously pay attention to the manner in which that knowledge is being taught; and both must overtly be embraced in a *pedagogy of teacher education*. (Loughran, 2006, pp. 3–4, emphasis in original)

The importance of the notion of a pedagogy of teacher education is rooted in an expectation that teacher educators need to articulate their knowledge of practice in ways that will offer insights into what they do, how they do it and why as they teach teaching. Developing a pedagogy of teacher education is not a veiled call for a “complete book of rules” about how to teach teaching, rather, it is a way of focusing serious attention on the need for teacher educators’ knowledge of practice to be more formally shared and critiqued in line with other scholarly traditions.

A pedagogy of teacher education involves a knowledge of teaching about teaching and a knowledge of learning about teaching and how the two influence one another in the pedagogic episodes that teacher educators create to offer students of teaching experiences that might inform their developing views of practice. Articulating that which comprises a pedagogy of teacher education therefore requires teacher educators to look into their teaching in ways that might capture and offer insights about the subtleties and nuances of their practice so that others might learn from, and build on, these research outcomes. Just as King (this volume) illustrates, that which might be “critical” to the research of learning about teacher education needs to be open to debate. If teacher educators share their approach to, and conceptualizations of, practice, they create opportunities for others to adopt, adapt and creatively respond to those insights in their own practice.

In developing a pedagogy of teacher education, the community of teacher educators needs to be able to illustrate how it is that students of teaching are educated (as opposed to trained). Through education, students of teaching might see that developing confidence in their own professional judgments as a consequence of explicating their pedagogical reasoning matters.

A pedagogy of teacher education offers the promise that teacher educators can demonstrate in their practice with their students of teaching that the core of expert practice is embedded in the need to make subtle judgements in unique situations (Hagger & McIntyre’s, 2000). In so doing, teacher education can create a worthwhile goal for
students of teaching to strive to achieve through their career long professional learning. To that end, looking into teacher education takes on new meaning so that the concept of teacher preparation might be better understood as just that; a beginning not an end unto itself.

LOOKING IN TO TEACHER EDUCATION

Cochran-Smith and Fries (this volume) “identify four dominant approaches to conceptualizing and studying “the problem” of teacher education during four overlapping time periods.” They highlight studying teacher education as a: curriculum problem; training problem; learning problem; and, policy problem. Through these different lenses for looking into teacher education divergent responses emerge and clearly represent very different expectations of the field over time. Importantly, they conclude that there is a growing need for “constructing the problem of teacher education in thoughtful, appropriate ways” and this is obviously most desirable. However, as has been alluded in both their work and this commentary chapter, “who it is” that constructs the problem impacts dramatically what is looked for and why.

A rich knowledge of teaching enmeshed in the subtle nuances of practice emerges from deeper understandings of pedagogy when the problems of teacher education are illustrated and worked with, mediated and managed, in the practices of teacher education itself. What a teacher educator frames as a given problem of practice at a given time may still revolve around any or all of the problems noted by Cochran-Smith and Fries; yet responding to each individually does not necessarily resolve the problem.

It is time for teacher educators to explicitly frame teacher education as being problematic in such a way as to illustrate that what they know, how they know it, why it matters and what it looks in practice is central to that which might be described as quality in teaching about teaching. Teacher educators are daily confronted by issues associated with (at least): the tacit nature of teaching (Polanyi, 1962); the theory-practice gap (Korthagen et al., 2001); the complexity of practice (Florio-Ruane, 2002); the tensions between developing students’ authority of experience and the allure of their authority of position (Munby & Russell, 1994); and, many more issues that impact what teaching about teaching looks like, and how learning about teaching is experienced. Each of these dilemmas, tensions, issues and concerns can of course easily be ignored so that the problem with teacher education can be framed by others. However, in a profession that understands what it does, how and why, the ability to speak for itself, to shape its own destiny and to seriously grapple with the expectations, needs and demands placed upon it is of paramount importance. Clearly, it is time for the work of teacher educators to boldly shape that which is the problem of teacher education and to respond in positive, well informed and meaningful ways. Seriously pushing ahead with an agenda for the development of a pedagogy of teacher education, I would suggest, is one such way.

REFERENCES

INTRODUCTION

The framing chapters for this section distinguish among the variety of methods used to do research on teacher education. Distinguishing among categories of research helps scholars understand changes in the field over time. More important, the categories can help researchers think about how they might engage in studies of teacher education. The categories are rough, but serviceable, groupings of research methods, purposes, and questions.

Much has been written about the strengths and weaknesses of varying research approaches, sometimes with the aim of promoting or defending an approach; sometimes with the aim of clarifying differences in fundamental assumptions. Discussions occur with an underlying sense that the quality of education research needs to be improved. Reports by the National Research Council (2002, 2005) have argued that the route toward improving “scientific” education research—a phrase chosen to acknowledge the legitimacy of non-scientific forms of education scholarship such as philosophy of education—is to adhere to general principles important to all scientific inquiry:

- pos[ing] significant questions that can be investigated empirically . . .
- linking research to relevant theory . . .
- using methods that permit direct investigation of the questions posed . . .
- provid[ing] a coherent and explicit chain of reasoning . . .
- replicat[ing] and generaliz[ing] across studies . . .
- disclos[ing] research to encourage professional scrutiny and critique.

(National Research Council, 2002, pp. 3–4)

The categories of research sketched in the preceding chapters aid in seeing differences among the groupings of questions, theories, and methods. That is, they show how some types of questions are linked to associated theories (implicit or explicit) and methods. Understanding these associations makes it easier to identify what questions fit with what methods and theories, helping researchers plan their work and helping readers decide whether a study has taken an appropriate approach.

Comparing categories of research on teacher education highlights issues connected to all of these principles. Rather than going through each principle, the discussion below considers three issues, each cutting across several principles: first, the issue of criteria for determining which research questions are significant; second the ways in which methodological constraints affect the choice of questions; third, the need for building trust in teacher education research.
HOW SHOULD RESEARCH QUESTIONS BE SELECTED?

A perennial issue in research on teacher education is how to determine what questions should be addressed. Ideally, questions should be both educationally and theoretically significant. That is, they should address issues of substantive value to the educational enterprise and add to the general understanding of education in ways that extend beyond the particular subjects and objects of study. The methods selected should then be ones that will yield the most trustworthy answers to the questions, given the resources available.

The framing papers and exhibits vary in the suggestions they make about how questions and methods should be selected. Gage (this volume) argues that research on teacher education should address the causal questions about what ways of teaching lead to pupil learning and what approaches to teacher education will, in turn, lead teachers to teach in those effective ways. The substantive value of the question stems from its focus on pupil learning, assumed to be a widely shared goal for education. The theoretical value of the question comes from the assumption that the causal connections identified will be found across a wide range of contexts. Gage’s article presumes that questions in research on teacher education should be selected by researchers, who gauge what issues are of educational importance and which theories should structure investigations.

King (this volume) takes issue with the idea that leading researchers should pick research questions, arguing that research on teacher education should address questions identified by those who have been ill-served by current education practices—especially questions identified by people of color. She also differs from Gage in the substantive touchstone for judging the significance of a question. For her, questions are not significant unless they are linked to critical understandings that will lead toward democracy and human freedom. Questions should be connected to critical social theory, highlighting the differences in power and privilege. Rather than having researchers with standing in the traditional social structure determine what questions should be addressed, King contends that those outside the dominant social structure should play the leading role.

Lampert (this volume), like King, believes that judgments about significance should be made by a group other than mainstream researchers. She says that education practitioners, rather than university academics, have “inside” knowledge of teaching that should guide the formulation of research questions. Those questions will often be context-specific, of immediate educational importance to the teacher. Theoretical contributions come through accumulating understandings about the nature of practice, rather than through learning about widely applicable causal linkages. Florio-Ruane (this volume) likewise views problems of practice as an important source of research questions.

Where Gage, King, Lampert, and Florio-Ruane promote attention to particular domains of research questions, the framing papers by Cochran-Smith and Fries (this volume) and by Borko, Whitcomb, and Byrnes (this volume) take a more neutral approach, distinguishing among several approaches, listing advantages and disadvantages of each. They optimistically recommend pulling approaches together, making links and drawing on the best from each option. Cochran-Smith and Fries cast differences as variations on the teacher education problem being addressed. Borko, Whitcomb, and Byrnes cast the differences as varying “genres” of research. Their effects and practitioner genres correspond roughly to the stances of Gage and Lampert, respectively. Their design genre is blend of these, with successive practitioner-oriented studies leading toward broader generalization.

Decisions about how questions should be selected, with related decisions about method, are obviously complex. They depend on value judgments, as well as reasoned analyses about what is already known, how answering additional questions would contribute to
theory and practice, and what chance a projected study has of yielding informative and credible answers. The value judgments themselves are complex. If the goal is social justice, does that imply selecting questions provided by students, teachers, or scholars from groups out of power? Or, as Sandra Harding (1992) claims, are marginalized groups also likely to be deceived about what will benefit them most? Will including diverse voices in setting research questions lead to greater equity or to a more accurate representation of teacher education’s operations and effects? Should these voices be included on democratic grounds? Or is science, and ultimately society, better served by allowing those recognized as experts within the research community to guide selection of questions? Such questions are vitally important, but contested. The quality of research depends on posing significant questions, but doing so, even deciding who should do so, requires careful thought.

WHICH COMES FIRST, THE METHOD OR THE QUESTION?

The theme of this section of the handbook is research methodology. The chapters and artifacts that make up the section demonstrate how closely intertwined are research methods and research questions. As discussions of how to improve education research (e.g. National Research Council, 2002) consistently emphasize, research methods should match the questions to be addressed. Questions about cause may be best addressed by experiments; questions about constructed meaning suggest ethnographic methods. And so on.

Standard advice in education research is to choose a research method to match the research question. Faculty cringe when a doctoral student begins a discussion of possible dissertation topics by saying what method they want to use, whether that be hierarchical linear modeling, auto-ethnography, or mixed methods. The professor will push back with, “What is the question you are trying to answer?” The presumption is that a student’s dissertation will be improved by formulating the question first, then designing research to answer that question.

Such admonitions are based on kernels of truth, but they create the impression that research plans are best formulated by selecting questions that seem most important or compelling first, then devising methods to address them. But doctoral students who take the advice literally often find that the question they develop cannot serve as the focus of a dissertation because it cannot be answered with the time and tools available. A question such as whether pupil learning is improved by having teachers complete programs accredited by NCATE, for example, matches current policy interests, but cannot be answered with much credibility by a doctoral student with only a year or two to devote to a study.

As, or perhaps before, researchers begin to pose significant questions, they should reflect on what methods are available to them, given their research skills, their talents, and the time they can devote. Their advisors will still likely push for clarity about the particular focal questions, or may suggest some investment in gaining additional research skills, but in any case planning for research requires joint consideration of question and method.

This reconsideration of the ordering of questions and methods should be undertaken by experienced scholars, as well as by doctoral students. For research on teacher education at any career stage, investigators should plan their studies through joint consideration of what questions are important and what methods are feasible. As Cochran-Smith and Fries show, the history of the research domain can be characterized by changes in the central research questions, but historical development of the field has been simultaneously affected by changes in the research methods scholars prefer. The choice of
method is affected by what questions seem important, but it will also be affected by the capacity for using methods and by the contemporary views about a method’s potential for producing trustworthy answers.

The bi-directional influence of question and method is consistent with the admonition that question and method should match. Recognizing that methods sometimes come first helps explain some of the disjuncture between what research is carried out and what questions are most often asked. Policy questions about the relative effectiveness of different approaches to teacher preparation, for example, are the dominant contemporary questions. Yet most research publications address other questions. The difference between dominant questions and current studies is explained, at least in part, by the methods most scholars prefer to use, or are constrained to use by the resources and tools available. The research methods appropriate for answering questions about effects of teacher education policies include econometric analyses of nationally representative data sets or controlled experimental comparisons of competing pathways to teacher certification. These approaches require a combination of specialized skills and data that only a fraction of current education researchers possess. Hence most of those doing research on teacher education will choose to address other questions, whether or not they agree that these policy questions are important.

Most faculty engaged in teacher education have teaching loads that give them limited time to carry out research. Moreover, they have few institutional resources, such as graduate assistants, survey research units, or travel funds, to support large-scale investigations. When these faculty engage in research, they are therefore constrained in the research methods they can use. The emergence of inexpensive internet based survey tools reduces some of the costs of large-scale research, but limited time allocated to research makes it difficult to invest time in developing valid and reliable survey scales and to carry out the follow-up needed to get high response rates. It is, then, reasonable for many faculty to select research questions that might be answered using small scale, inexpensive research methods. The appeal of practitioner research is obvious.

If limited research resources mean that most studies of teacher education will be modest, practitioner studies, then it is no surprise that most published research on teacher education addresses the questions to which these studies are suited. These include questions about what the practice of teacher education means to those who engage in it, how prospective teachers interpret their opportunities to learn, and what they learn from the particular experiences in their programs. Such work is what Lampert and Florio-Ruane advocate and what the framing chapter, Borko et al., classifies as interpretive. The examples Cochran-Smith and Fries offer to illustrate work on the problem of teacher learning likewise address such questions.

As the authors in this section note, interpretive and practitioner research poses particular challenges for communicating what is learned in ways that allow readers to go beyond the single case. As studies in disciplines from anthropology to political science demonstrate, close analysis of single cases can shed light extending beyond that case (Firestone, 1993; King et al., 1994). To provide trustworthy bases for generalization, it is particularly important for researchers to attend to the principles regarding an explicit chain of reasoning, generalization and replication, and disclosing research to critical scrutiny.

BUILDING TRUST IN RESEARCH ON TEACHER EDUCATION

A persistent complaint about education research is that its quality is low (e.g. Kaestle, 1993). Recent syntheses found that research on teacher education is no exception; for
research on central questions such as the effect of subject matter courses or the effects of teacher education policies, few studies were found to be of high quality.

Greater trust in education research is needed across all areas. To build trust, it will be important to provide explicit chains of reasoning, to give enough information to allow for replication and generalization, and to disclose research methods to professional scrutiny. Too often, interpretive and practitioner research studies do not describe enough about the research methods used or the analyses done to make the chain of reasoning leading to conclusions clear to the reader. This is a failing of the individual research articles, not of the research method itself. As Erickson (1986) has argued, rigorous procedures can be used to give readers of qualitative research reports a good basis for trusting the interpretations and conclusions drawn. Both Lampert and Florio-Ruane recognize this problem, noting that practitioner research too often results in storytelling without sufficient attention to the details needed to understand the basis of the story or the connections to theory and without enough discussion of the other research that would put the story into context and make its purpose clear.

The need for greater clarity about methods used in data collection and analysis is not unique to practitioner and interpretive research. Teacher education studies using large samples, surveys, and structured interviews and observations also need to be explicit about the bases for drawing conclusions from their studies. An endemic problem is that the surveys and other data collection instruments used are not accompanied by information about the degree to which they have been tested for reliability and validity.

For research on effects or on policy, reports often offer too little explanation of the chain of reasoning from data to conclusions. Gaps in the chain may come from unclarity about the connections between the names for features and outcomes under study and the tools used to measure them. Lack of connection to theory is often a problem here, too. Studies are guided by implicit theories that seem to have a basis in common sense, but lack conceptualization of the ways in which the components are believed to interconnect. For example, studies of teacher certification presume some connection between certification and teacher effectiveness, but the basis for that connection is ambiguous at best. One possible connection would be that completing the requirements for certification makes it likely that a teacher can produce at least some minimum amount of pupil learning. That presumes that requirements and minimum scores on teacher tests are set with the intent to ensure that all teachers have attained a minimum level of knowledge and skill. But the intent of those setting minimum test scores is seldom known.

One final way in which trust in research is undercut comes when researchers also become advocates. Because education is an applied field, researchers are often asked about what should be done. Some researchers initiate entry into debates about best policy and practice. Because of their expertise, researchers should have a role in policy debates. Their credibility, however, can be undercut when they are identified as advocates, rather than experts. Researchers must, as much as possible, make clear when they are speaking as experts and when they are speaking as advocates.

CONCLUSION

Research on teacher education can be usefully divided into several categories. The categories have distinctive clusters of questions, purposes and methods. Understanding the differences among these categories gives researchers a better sense of the choices they can make. Those choices should attend to what is already known and to the issues that
are current in the field. Choices should also be driven by the educational values an investigator wishes to promote.

The questions that researchers will address are also dependent on their own skills and the resources on which they can draw. Some questions can only be productively addressed by costly, large-scale studies. Such studies require the support of major institutions, whether these be universities or funding agencies. Only a small fraction of those interested in studying teacher education will have the opportunity to lead such studies, though many others may be involved in some way. For many people who wish to do teacher education research, the resources they have available will lead them to do small scale studies focused on practices in particular courses or experiences.

The authors in this section argue that such studies can make valuable contributions to our understandings of practice, but they also warn of the difficulties in doing interpretive work that allows for understandings that go beyond a single particular case. Such intensive work can add to collective understanding, but only if reports include the detail needed for readers to evaluate the reasoning about the case and to think about the light it sheds on other cases.

Those working on studies in other genres also face challenges to making their work credible to a variety of audiences. For all research genres, it is critical to give the reader enough information to understand the chain of reasoning. Chains of reasoning in survey studies, for example, include assumptions about how respondents interpreted the questions, what motivated their responses (e.g. trying to please the researcher, trying to give the socially acceptable answer), how individual survey items were combined to make up broader scales, and so on. Readers need to see that chain of reasoning to have a basis for trusting a report’s conclusions.

Many approaches to research on teacher education can make productive contributions. With appropriate levels of support, trustworthy answers may be offered for the central questions in today’s debates. Critical interpretive studies can contribute to our understandings of the complexities of teacher education and may change the terms of debate.

REFERENCES

I begin with a disclaimer and a confession of sorts. I come to teacher preparation as a researcher from a rather far-removed field. I have always been interested in education and teaching as a field partly because I grew up in the home of a high school English teacher. At the same time, the focus and practicality of economics as a way of thinking was attractive to me from an early age. I became an undergraduate economics major, but continued to be interested in teaching and learning, and pursued what by today’s standards would count as an alternative route into teaching. As a third grade teacher, I was very struck by how many resource allocation decisions I was making and all this prompted me to try and combine my interests in the fields of education and economics in a graduate program.

I first encountered the process-product teacher effectiveness research literature as a novice graduate student, and recall being determined to master the literature and to become quite knowledgeable about what we know about links between processes in classrooms and learning outcomes for students. I struggled unsuccessfully to understand the process-product literature. I have memories of making endless charts about what seemed to make a difference under what circumstances. I have further memories of failing to make sense of these charts and ultimately feeling there was something wrong with me since others seemed so convinced that progress was being made. Scarred though I was, I soldiered on.

DISCERNING THE EDUCATION PRODUCTION FUNCTION

Given my economic disciplinary orientation, I tried to square the process-product research tradition in education with the production function research tradition within economics. Permit me to use the production function terminology as a shorthand for whatever there is about teaching and learning that is systematic and predictable. Notice that by formulating the concept in this fashion I am introducing the possibility that there really may be no such thing as an education production function.

It is abundantly clear that there is no such thing as a simple or straightforward education production function (Monk, 1989, 1992). If it did exist, simple and straightforward interventions like providing additional training of a particular type for teachers or hiring teachers with certain pre-specified characteristics would translate with considerable certainty into desired outcomes like increased pupil performance. The fact that the evidence is so inconsistent with the idea of a simple production function introduces complexity into the debate, a point Florio-Ruane (2002) articulates quite clearly.

Complexity makes life more difficult for the analyst and we must find ways to control
for the sources of complexity. This sets the stage for more powerful research techniques—experimental studies and multivariate statistical designs being some examples. It also sets the stage for narrowing the focus of questions with the attendant risk of losing the ability to answer the more general questions that tend to be of interest to practitioners and policy makers. Several of the authors in this section of the Handbook comment on this dilemma. For example, Borko and her colleagues note the limitations of process product research because of its failure to deal with how people construct meaning in classroom settings (Borko et al., this volume). Florio-Ruane (2002) observes that efforts to generalize the results of teacher effectiveness studies are often thwarted by the contextual, local, and situated nature of teaching and learning. I am reminded of the old quip about academics knowing more and more about less and less until they know everything about nothing.

Complexity also sets the stage for an infinite regress as when we go on and on, slicing things ever more finely in our efforts to discern regularities. Disappointing results prompt efforts to go deeper and there really are no well worked out rules for assessing whether or not actual progress is being made toward understanding the properties of the elusive production function. Economists (and others) have limited tolerance for delving ever more deeply into the black box. Some finesse the problem by focusing on outcomes and emphasizing the importance of creating clear goals and the proper incentives for the various players, including teachers, who have influence over the endeavor (see, for example, the volume edited by Hanushek and Jorgenson, 1996). From this perspective, it matters less how one gets to the goal than being able to show that the goal has been achieved—with rewards distributed accordingly.

Education researchers, in contrast, are a hearty lot and seem undaunted, even in the face of very discouraging results. Pam Grossman’s conclusion about there being few definitive conclusions that can be drawn about the effectiveness of micro teaching, as reported by Cochran-Smith and Fries (this volume), is quite devastating in my mind since she calls attention to a host of serious problems including a lack of reliability and validity analyses of the instruments and discrepancies between appraisals. But notice there is nothing in Grossman’s conclusion to preclude new efforts to understand micro teaching, presumably using instruments with better reliability and validity properties.

THE POLICY CONTEXT

Not all questions about the effectiveness of teaching and the preparation of teachers are equally important to answer, and for me the questions that matter the most are those whose answers make a difference in the life chances of learners. I do not worry as much as Florio-Ruane (2002) about privileging one research tradition over another. If one research tradition is better equipped to answer the pressing questions of the day, so be it and let us embrace the approach and take advantage of what we learn. However, it is also important to be on guard for pretenders and the ease of convenience. Just because something is relatively easy to measure should not entitle it to predominance in the debate.

Moreover, the mixing of research methodologies for its own sake has little appeal to me. Researchers come from different orientations and know about and embrace different research strategies. They work in different parts of the field and properly focus on honing their skills as researchers. They learn from one another and do so largely by reading and critiquing each others’ work and participating in the overarching scholarly debates. Even if we grant the premise that all these multiple perspectives have value to add, it does not
follow that the best strategy involves simply mixing them together. Effective collaborations and inter-disciplinary studies are more difficult to achieve than the rhetoric sometimes suggests. Where the question needing an answer lends itself to cross disciplinary efforts, it makes sense to pursue these, but we should resist falling in to the trap of thinking that just getting people from different perspectives together will somehow lead to useful results. For me the key is to settle upon what questions are the most important and to then choose the relevant research strategies.

My practical bent is also rooted in my current set of responsibilities since I am in an administrative role in a research oriented college of education with a quite large pre-service teacher preparation program. I find myself engaged in making design decisions with remarkably little research based evidence to provide guidance. For example, we recently decided to change the type of supervision we provide during our student teaching experience. Heretofore, we relied upon generic supervisors who worked with student teachers in many different content areas. A given supervisor might be supervising a student teacher in secondary mathematics one day and a student teacher in secondary English the next. As part of our effort to strengthen the content preparation of our aspiring teachers, we shifted to supervisors with content-specific expertise so that one supervisor with a background in secondary mathematics would supervise only student teachers preparing to become secondary mathematics teachers. While this seems like a desirable change on its face, I was very struck by how little guidance there was in the literature to support making such a change.

I hasten to point out that the change was not without its critics. A number of our students were unhappy with the change since it basically meant that we had to group student teachers geographically by subject area. Currently at Penn State, if you wish to become a secondary mathematics teacher, you need to student teach in the Pittsburgh area where we have located our secondary mathematics supervisors. Previously, there were more degrees of freedom regarding the location of student teaching sites and this was a benefit for students since it is not convenient for all of our mathematics education students to move to Pittsburgh. When quizzed by students about why we made the change, I found myself talking about how research has demonstrated the importance of subject-specific pedagogical knowledge. While I can certainly point to some studies that reach this sort of conclusion, I must also concede that I am not aware of any study that assessed the impact of changing student teacher supervision in precisely this fashion.

Other costs were associated with the change and perhaps the most obvious is the increase in the salary we needed to pay supervisors. It is easier to find generically trained supervisors and as a consequence we had to increase our stipends to attract reasonable pools of candidates. Can I demonstrate additional benefits to justify these increased costs of our program? Not really. Perhaps this will become possible as we become better at tracking the successes of our students, but it is hard to demonstrate currently. The bottom line is that we made a fairly significant and costly change in our teacher preparation program with only limited support from the research literature. And yet, I think it was the right move to make, largely because of the compelling nature of the face validity of the underlying logic.

**SOME IMPORTANT TWISTS TO KEEP IN MIND**

As I ponder questions about what we need to know about teacher effectiveness and preparation, I am reminded of a taunt a colleague was fond of making to teachers. He
would take some delight in making the assertion that “teaching is a weak treatment.” If we strip away the hyperbole and self-serving rhetoric that is so often on such bright display in our field and focus on the mind-numbing nonsense that sometimes goes on in the name of teaching, many will be tempted to think he is right, but grudgingly so. And here comes an important twist: even in at its drab, mind-numbing worst, teaching on occasion can prove itself to be truly transformational. Teachers and educational institutions in the real world and even in the face of all the pressures of the day can and do transform lives.

A second twist to keep in mind is that just because current practice has a drabness associated with it, nothing says that it has to be this way. Just because the education production function we are living with is complicated and ill-behaved and perhaps a bit drab, it does not follow that it has to stay this way. In other words, the production function itself is something we have created and it is not immutable. We can change it and make deliberate efforts to change how it is that teaching and learning take place. So, in addition to trying to study and deduce the properties of the education production function, the task at hand can be extended to include efforts to try and change its nature. This could have horrific implications as in trying to make learners compliant to ill-designed teacher proof curricula or quite empowering as in stimulating genuine inquiry on the part of teachers, students, and administrators.

SOME SUGGESTIONS TO CONSIDER

As we seek to learn more about the impact of teachers and teaching so that we can improve practice and more routinely achieve transformational results, I offer the following suggestions:

- Be clear about the question you are trying to answer, frame it narrowly and be clear about why it is important;
- Be explicit about methods and why you are choosing them;
- Be willing to make your data available to others;
- Anticipate critiques and do what you can a priori to address them;
- Be measured in drawing conclusions;
- Situate your study in the existing literature so that your study builds on previous efforts; and
- Be mindful of the political environment into which your findings will emerge and recognize that you have some obligation to assist consumers in understanding the results of your research.

The design studies described by Borko et al. (this volume) are consistent with these ideals and seem quite promising for the field. It is heartening to see instances like these of powerful studies that are so rich in potential for improving the practice of teaching.

Part 9

What good is teacher education?

The place of teacher education in teachers’ education

Editor: Mary M. Kennedy
Part 9
Framing chapters
One of the most enduring and most contentious questions involving the education of teachers has to do with defining an education that would genuinely enhance the quality of teaching practice. One problem is that, as a society, we hold different ideals for good teaching. In one ideal, the teacher plays a cultural role, representing an educated person. In another ideal the teacher is a nurturer who helps young people grow, learn and develop. In another the teacher is a political actor, striving to right social wrongs, and in yet another the teacher is a professional with specialized expertise. With so many different notions of what makes someone a good teacher, it should not be surprising that there are different notions about the kind of education that would produce a good teacher.

Colleges and universities respond to this dilemma by providing a bit of everything to the aspiring teacher. Teachers are not educated in isolated programs such as those attended by aspiring lawyers, doctors or architects, but instead are educated by the entire institution. The full institutional program is presumed to make teachers into educated adults, while one part, which is explicitly labeled “the teacher education program,” is presumed to make them into professionals with specialized expertise. Labeling the professional portion of the program “teacher education” is somewhat misleading, since teachers presumably benefit from their entire college education, not just from that narrow segment that is labeled as such. But because we hold so many different ideals for good teaching, this segment of teachers’ education, the piece that is called “teacher education,” is the most contested part of teachers’ education and is the focus of the papers presented here. Let’s call this the Official Teacher Education Program, or OTEP. Questions of interest here are: Is the OTEP really necessary? Does it improve the quality of teaching? What does it accomplish, or what should it accomplish?

The papers in this section address these questions. They recognize that the OTEP is one part of teachers’ education, and they recognize that there are enduring questions about this piece. In light of the rest of teachers’ education, perhaps this part isn’t really needed. How can we be sure that it provides something that really adds value to teachers’ overall education? These are the questions taken up here.

There are at least two dimensions to arguments about the OTEP portion of teachers’ education. One dimension has to do with the character of the knowledge needed for teaching, and whether that knowledge is essentially vocational or liberal. Vocational knowledge is usually presumed to have a direct application to specific situations, whereas liberal knowledge is presumed to provide ways of perceiving and understanding situations. Disagreements on this issue reflect not only different ideas about teaching, but also differences in assumptions about how knowledge influences human activity in general. The second dimension of the dispute has to do with the content of the knowledge needed for teaching. Here, advocates debate the relative importance of specific courses. A common argument, for instance, has to do with the relative importance of knowing the
content to be taught versus knowing about teaching itself. Usually, content is offered by the institution as a whole, but the OTEP portion may focus only on teaching itself. Arguments about the value of specific content differ from arguments about the character of teachers’ education in that advocates on both sides tend to focus on the vocational value of the content, so that the liberal value of being an educated person is obscured.

These two dimensions are rarely cleanly separated in arguments about teacher education, but each yields distinct criticisms of the OTEP portion of teachers’ education. Advocates for a liberal education dislike the OTEP because it is generally perceived to be vocational rather than liberal. They also fear that these courses may actually deter bright, liberally-inclined young people from choosing teaching careers because such people are not interested in vocational courses. Advocates for the value of content knowledge as a vocational ingredient tend to dislike the OTEP because they don’t believe it is really vocationally necessary. In addition, they worry that the time required for the OTEP may replace time that would have been better spent acquiring more subject matter content. In each case, the value of the OTEP is challenged, though the reasons for the challenge are quite different.

The phenomenon of the OTEP is like the famous duck/rabbit optical illusion shown in Figure 58.1, whose entire interpretation can shift from moment to moment even though the phenomenon itself remains unchanged. Different perceptions of the OTEP often follow from different assumptions about the nature of teaching, different assumptions about the nature of knowledge, and different assumptions about how knowledge influences human actions. It should not be surprising, then, that different people draw different conclusions about the role and value of the OTEP.

This section aims to both examine and illuminate these different perspectives regarding the role of the Official Teacher Education Program plays in the overall education of

Figure 58.1 The Official Teacher Education Program as a duck/rabbit problem.
teachers. Both the historical artifacts and the new contributions reflect different points of view and different assumptions about how that particular piece of teachers’ education adds to their entire educational experience and what it adds, if anything.

FRAMING CHAPTERS

We have three framing chapters, each with a different slant on the question of how to educate teachers.

The first paper, from Steve Weiland, examines the OTEP—not as a vocational training opportunity but as an opportunity for young adults to be liberated from the confines of their own narrow experiences. An advocate for liberal education, Weiland also acknowledges that the keepers of liberal education, the liberal arts faculty, are themselves in a quandary now, as they re-examine fundamental questions about canon, knowledge and the role of education. Weiland examines different interpretations of the term, “liberal education” and argues that liberal education is important for teachers because their authority as teachers derives from their education. In an interesting turn-around, Weiland also notes, though, that contemporary higher education has not done a good job of providing any of its students with a strong liberal education and argues that the OTEP could enhance teachers’ overall education by stepping in and filling this gap. That is, Weiland’s view of the role of the OTEP is not to provide a technical, research based education but to provide a liberal education, one that helps intending teachers learn to see multiple points of view, to critique arguments, to reason, and to see connections among ideas. His argument is that the OTEP would be stronger if it became more liberalizing, rather than more professionalizing.

The second paper, by Frank Murray, focuses on the need for OTEP by asking about the nature of teaching itself. He suggests that critics of the OTEP assume that teaching is a process that comes naturally to human beings and that requires no special training. But, he notes, the kind of teaching that comes naturally, a form of “show and tell,” is not very well suited to the institutional context in which contemporary teaching occurs, nor to the kind of abstract content that comprises our curriculum. Murray suggests that, if teachers are to produce genuinely educated students, with deep understanding of school content, they do indeed need the OTEP. And, more specifically, Murray’s view of the value of OTEP is that it should provide teachers with a technical education, filled with vocationally-relevant content largely deriving from research.

These papers, as a pair, reveal the tension between liberal and vocational education even within the OTEP. Both of these authors argue that teachers’ overall education needs to include the OTEP, but they see its value in very different ways. Yet they both argue that this piece of teachers’ education needs improving. So even though both believe there is a genuine need for the OTEP, they define the need in quite different ways and neither believes the OTEP, as currently configured, achieves the needs they identify for it.

The third paper, by Kennedy, Ahn and Choi, looks for evidence that educational course content actually benefits teachers’ pupils. It asks, to what extent do the courses teachers take in college make a difference to their students’ learning once they become practicing teachers? It takes up three hypotheses about teachers’ education: that they need the pedagogical knowledge provided by the OTEP, that they need content knowledge provided outside the OTEP, and that they need, more than any specific courses, to be generally bright and well-educated people. The authors seek out and examine empirical studies for evidence that different types of educational backgrounds, and
specific portions of the college curricula, demonstrate greater benefit than others educational backgrounds do, when we look at how much teachers’ pupils learn from them.

ARTIFACTS

The earliest paper we present was originally published in 1920, and then reprinted in 1965 in a collection of readings edited by Merle Borrowman. The original authors, William Learned and William Bagley, were asked to assess the status of normal schools in Missouri but they used the occasion to consider the deeper question of role and purpose for teacher education. They note that normal schools were initially designed to provide a purely vocational education for teachers, not a general education, and moreover, this vocational preparation was almost entirely devoted to matters of technique, not content. Content was provided only in cases where the teacher clearly needed basic education. However, over time, normal schools started thinking of themselves as local colleges, or as stepping stones to other colleges. Students began attending normal schools not to prepare for teaching, but to prepare for a college education. Learned and Bagley are unhappy about this drift in purpose. They argue that normal schools should return to their original mission and should make all curriculum decisions from the perspective of a genuinely professional purpose. The programmatic details of teacher education have changed substantially since Learned and Bagley wrote this paper—indeed, the evolution is now complete as virtually all normal schools have evolved into regional state colleges or universities, offering general education programs to all students. But their paper provides a good example of an argument for a purely professional approach to teacher education, a good sense for the tension between liberal and vocational education, and an interesting picture of what teacher education looked like in the early 1900s.

The second historical artifact was originally published in 1963 as a chapter in a book examining the role of the OTEP within a teacher’s college education (Conant, 1963). Like Learned and Bagley, Conant was also conducting a Carnegie-commissioned study of teacher education. His book summarizes his findings and includes a number of recommendations, mostly directed toward state education agencies. But his opening chapter, “A quarrel among educators,” reprinted here, describes the animosity he sees between education faculty and disciplinary faculty. He finds that discipline faculty want to minimize education courses, but at the same time, they don’t want to sully their hands with problems of public education. Conant’s examination of teacher education helps us see how much teacher education had changed since Learned and Bagley’s examination. By the time Conant conducted his investigation, normal schools had evolved into colleges and universities and were subject to numerous state rules about their curricula. But Conant’s examination also shows us that the argument about what the OTEP should look like was even more bitter in the early 1960s than it had been 45 years earlier. Conant suggests that debates within the professorate, and the eventual entry of laymen into that debate, led to certification rules in most states, which did not resolve the question but merely added yet another layer to it.

The third artifact, by Gary Sykes, was originally published in 1984, and provides a view of teacher education after another pair of decades has passed. Sykes examines the difficulty teacher education has had in establishing itself as a legitimate occupant of the higher education community, and the difficulty it has had establishing its legitimacy in the broader education community. He examines a number of reform efforts that rose and fell since Conant’s examination of teacher education and reviews the reasons for their failures.
RESPONSES

Three discussants respond to these papers and the discussants also represent different points of view. Diane Ravitch, a historian, puts both the papers and the issue into a historical perspective. Linda Darling-Hammond, a teacher educator, puts the issue into a professional perspective, considering the question of teacher education in light of the professionalism granted the graduates of teacher education programs. Frederic Hess, a policy analyst, examines the papers from a policy perspective, re-casting the issue in terms of options available to policy makers who must respond to these disagreements.

A reading of the entire set of papers helps us understand why this issue is never entirely resolved. The optimal education for teachers depends in part on social values, in part on the financing and management of schools, in part on the interaction between different departments within the university. Ultimately, though, it also depends on our ability to understand the mystery of teaching, the things that enable teachers to enter the minds of other human beings and cause learning to occur in those minds. If this ability results from a specific knowledge base, we are still at a loss as to what is in that knowledge base.

REFERENCES

Are we meeting our educational obligations to prospective teachers? Consider how Bard College president Leon Botstein (1997), also a scholar of European history and leading figure in classical music, described the situation of students entering American higher education, including of course, those planning on teaching careers.

Is there for the American adolescent the social supports for the love of learning, for curiosity, for the discipline that must accompany inquiry and then access to the pleasure of the life of the mind? . . . In fact, in our history as a nation, we have never had a comparable moment in which, at any level of schooling, the encouragement of learning and curiosity has received less support, spiritually and practically, from the adult world.

As Botstein knows, relations between liberal education and professional studies have confounded college and university faculty and administrators, students, and higher education policy makers for decades. Teacher educators of course align themselves with Botstein’s attitude toward learning. But like their students, they are increasingly remote from liberal education and the intellectual opportunities it offers, if not indifferent to it. The goal of this chapter is to explore how liberal education might be made more important in teacher education, to teacher educators and prospective teachers alike.

For most American college students the undergraduate curriculum is simply a sequence of courses leading to a degree. Its rationale is as obscure as its origins in the liberal arts as they were formulated in antiquity. The part of the curriculum that came to be called “liberal education” in the U.S. more than a century ago signified the hope that a college degree would provide something durable for young adults, a course of study in the humanities and the social and natural sciences, that would “liberate” them from the limits of their experience and add historical, philosophical, and other perspectives to what was learned in preparation for a career. Liberal education stood primarily for knowledge of the past, great works of literature (the controversial “canon” in the “Culture Wars” of recent decades), principles of science, and other domains presumed to be valuable for individuals and for democratic society. In a paradox, liberal education conveyed tradition and represented ways of being critical of it. It has been, at its best, a resource for intellectual independence, personal development, and reflective citizenship.

When aspiring teachers think about the teacher education curriculum they are like other students; primary attention goes to completing the requirements for launching a career. They seek certification in courses on teaching methods and some form of supervised classroom teaching, but are generally asked to be only minimally prepared in academic subjects, much less in liberal education. Indeed, between the now well known “apprenticeship of observation” (Lortie, 1975) preceding college, when prospective
teachers learn about elementary and secondary teaching as students, and “induction” into the profession as a teacher learning from practice (Hoy & Spero, 2005), the undergraduate years can appear to be merely an interlude in which the practical value of prior classroom experience is suspended while the academic and bureaucratic machinery of certification performs its state-sponsored functions, primarily focused on matters of teaching methods. We can expect most teacher education students to wonder, if they don’t actually ask, “What should I know that will make me an effective teacher?”

In the view of the Carnegie Corporation teacher education shows little interest in liberal education, thus this recent statement of its meaning for prospective teachers is surprisingly direct, based as it is on the place of learning in any legitimate profession.

[Teachers’] professional authority will rest in a significant extent upon their ability to demonstrate that they are themselves educated persons. Therefore, teacher candidates must be expected to know more in the way of subject matter than just what they are charged with teaching. Teacher candidates must command general education, liberal education, and the liberal arts.

(Carnegie Corporation, 2001, p. 3)

But the Corporation’s eagerness for better educated “Teachers for a New Era” (the name given to the major reform project it is sponsoring) reflects expectations for a part of the undergraduate curriculum that is by no means as secure as it once was. Teacher education is asked to make more concrete and visible the uses of liberal education for its own purposes. This chapter takes up conditions for such a change in the teacher education curriculum.

The timing does not appear right for such a commitment. Recent accounts of what teachers should learn as undergraduates ignore liberal education (Hiebert et al., 2002; Brouwer & Korthagen, 2004; Darling-Hammond & Bransford, 2005). And liberal education is now an uncertain enterprise without a consensus about its goals and practices, or how the prescribed curriculum of the past can be fitted to the proliferation of new fields and majors generally indifferent to intellectual tradition (Edmundson, 1997; Brint, 2002). American colleges and universities, with our elementary and secondary schools, now mainly serve “vocationalism” (Grubb & Lazerson, 2004). Thus, despite the optimism of some observers (Lemann, 2004) most students appear to see little value in courses beyond what contributes to their majors and, in their view, to their prospects for jobs and careers. If the Carnegie outlook is correct, then prospective teachers, and their teachers in teacher education programs, should be among those resisting such a trend. Thus, this chapter addresses the question “What role should liberal education play in teacher education?” It argues that the best opportunity for liberal education in teacher education will come from within the latter in conjunction with whatever else makes up a student’s degree program. Thus, teacher education should adopt those goals of liberal education which can strengthen its programs and their impact, and its institutional and social position.

The chapter offers a review of the meanings associated with the phrase “liberal education” as it is offered at the different kinds of institutions with teacher education programs. The review identifies those features of liberal education that have made loyalty to it so durable and practice of it so contested. There has been, seemingly, a “crisis” in liberal education since Harvard adopted the elective system more than a hundred years ago and prompted a debate about what all American undergraduates should be asked to study. Attention then turns to teacher education and its stake in liberal education, focusing first on the question of professionalism and the teacher’s “knowledge base,” a
necessary framework for considering any role for liberal learning. The longest section of the chapter explores how teacher education might move toward liberal education, by incorporating into its curriculum attention to practices proposed recently by leading scholars in the humanities who have also demonstrated interest in teaching at all levels, and by applying such ideals and practices to the education of teacher educators. A brief conclusion is based on the chapter’s title and what will be required if there is to be any closing of the distance between teacher education and liberal education.

LIBERAL EDUCATION: THE GOLDEN AGE AND AFTER

The influential psychologist Jerome Bruner (1996) identifies many of the problems of the curriculum with these questions:

Should education reproduce the culture, or should it enrich and cultivate human potential? Should it be based on cultivating differentially the inherent talents of those with the best native endowment, or should it give priority to equipping all with a cultural toolkit that can make them fully effective? Should we give priority to the values and ways of the culture as a whole, or give pride of place to the identities of the subcultures that comprise it?

(p. 80)

In its reflection of these choices the college curriculum resembles the elementary and secondary ones, Bruner’s primary concern. Thus, school subjects and then academic disciplines (old and new) are made to represent a variable configuration of complementary and competing interests. And the curriculum is a product too of history and social change, making the coordination of its intentions with what actually happens in the classroom often problematic and never perfect. Liberal education has been celebrated and reviled for its role in “cultural reproduction,” though most of its partisans would abjure such a phrase. Bruner does not mean to suggest that choosing between the options he proposes is a simple matter. He knows that no curriculum represents a precise and unambiguous response to any or all of his questions.

Despite the fact that many teachers have presumably been educated to teach the primary subjects of the liberal arts (literature, history, etc.) there has never been a strong role for liberal education in teacher education, with many teacher educators seeing it as elitist or indifferent to the demands of “practice” or “pedagogy.” In the late 1960s, the organizer of a national conference on the liberal arts and teacher education did ask “why the two are not essentially one and the same thing.” But the book derived from the conference carried the less optimistic and more honest title, The Liberal Arts and Teacher Education: A Confrontation (Bigelow, 1971). They “confront” each other because of their seemingly contrary assumptions about the purposes of the undergraduate curriculum, the academic vocations, and the nature and uses of the university. Traditional liberal education, centered on the humanities and the social and natural sciences, favors the history of ideas and theories, the authority of the disciplines, and an image of the university as apart from society, or detached enough to support critical perspectives toward its social institutions. Teacher education favors practice, has on campus an intellectually subordinate relation to the disciplines of the liberal arts and sciences, and, because of its relations with schooling represents the university’s obligations to society. In the 1990s the influential philosopher of education Nel Noddings’ recommendation that liberal education (or what was left of it) be abandoned in favor of “care” as the
primary subject of the curriculum was well received by teacher educators. “Relation,” she argued, “precedes any engagement with subject matter” (p. 36).

Since the middle of the last century there have been periodic expressions among teacher educators for more integration of their efforts with liberal education (recent examples include Reagan, 1990; Coleman & DeBay, 2002; and Trubowitz, 2004) and occasional expressions of regard for the work of K-12 teaching among scholars in the disciplines of the arts and sciences (e.g. Graff, 2003). But the gap between the two academic domains appears to be unbreachable. The differences are not absolute of course; scholars cross boundaries, as examples later in this chapter demonstrate, and projects of reform sometimes include cooperation across the liberal and teacher education divide (e.g. Murray & Porter, 1996). Yet, as is often lamented, specialization reigns in academic work together with territorial prerogatives and suspicions, even when developments in the organization and production of knowledge, like the new information and communications technologies, pose compelling problems of teaching and learning across sectors.

What is liberal education?

Perhaps if there was a universal definition of liberal education it would be easier to enlist teacher educators in supporting its role in the curriculum. But defining liberal education is as challenging as defending it in a time of increasing focus on the college years as merely preparation for jobs and careers. In the Carnegie Corporation statement, for example, as is often the case, general education and the liberal arts appear to be conflated with liberal education. There are reasons to do so reflecting intention if not practice in American colleges and universities.

Yet, general education is better understood as something different from liberal education, reflecting a pattern of distribution requirements, as in Harvard’s recent adoption of a format popular at many other institutions. Students choose from a menu of courses, rather than taking a prescribed group of courses in arts and sciences disciplines that represent a particular idea about learning goals.

The “Report” announcing Harvard’s latest reform includes a useful statement of difference. Thus, general education represents “an overview of knowledge [that] insists on the value of learning in more than one discipline and specialization,” while liberal education—though it can contribute to such an integrating function—has as its goal demonstrating “the value of ‘disinterested’ learning-knowledge for self-development-aside from any specific informational or use value the learning may also supply” (Committee, p. 4). Finally, the phrase “liberal arts” can suggest work in the humanities and the fine and performing arts if it is not amended to recognize also what is required in the study of science and mathematics. And the phrase “liberal learning” also deserves consideration, signifying as it does an activity taking place beyond the years of formal degree-seeking education, or “professional development” in the case of teachers.

Liberal education is still the best phrase to describe what is desired of students before or outside the college major, or ideally (and certainly for teachers) in conjunction with it. Definitions come in many forms. Some scholars prefer a genealogical approach, focusing on how liberal education in the U.S. today still reflects its origins in the debates over it in England in the nineteenth century. Thus, historian William Carnochan (1993) finds there the wish to heal “the deep, twin wounds of commercialism and professionalization, an argument that has survived and flourished in the commercial and professional setting of the modern university, where liberal education is looked upon as a way of staying human in a world of inhuman practices” (p. 29). Others recast such foundations in more recent
intellectual vocabularies, as in the judgment of American liberal education as an expression of Pragmatism, the nation’s distinctive form of academic philosophy (Kimball, 1995). In this version, seen from the perspective of increasing institutional and public uncertainty about the meanings and uses of liberal education when it is organized around classical forms of learning, there are key roles for multi-culturalism, community services, and assessment.

Whatever the origins of liberal education, the steady growth of the “practical arts” threatens their durability simply because a smaller and smaller percentage of American students have any sustained exposure to them (Brint 2002). In fact, at all but the leading research universities, the “practical arts” (including education) now make up the core of teaching and learning as the liberal arts did in the middle years of the twentieth century. These are the institutions where most American teachers are educated (at least formally), the locations of the “Education Gospel” giving increasing priority to “vocationalism” above all other educational values (Grubb & Lazerson, 2004). And many of their students are transfers who wind up cobbling together whatever liberal education they can gain (or are required to have) apart from any idea about its uses including its relation to teaching (Schneider, 2005).

Contemporary uncertainty about a definition of liberal education reflects a breach between approaches to undergraduate learning that specify what a student should know, or what he or she should be able to do. Thus, for some advocates, liberally educated students should have knowledge of the past, of durable works of literature, of essential scientific ideas and theories, and of the habits of mind characteristic of the disciplines in which these are studied. For historian Donald Kagan (1999), such a prescribed curriculum yields “serious talk on serious subjects based on shared knowledge.” Inevitably, he favors knowledge of the past as the core of liberal learning, of “human experience through the ages, of what has been tried, of what has succeeded and what has failed, of what is the price of cherishing some values as opposed to others or of how values relate to one another” (pp. 222–223). There is here a strong normative tone, typical of many critics of higher education who find a lack of substance (or subject matter) in what is now mis-identified as “liberal education.”

In arguments for liberal education, of course, scholars and teachers often speak with the authority of their own educational accomplishments. Charles Anderson (1993), a political theorist, believes that the meanings of liberal education are most visible in professional behavior.

The true professional does not simply follow doctrine but examines doctrine, critically, aware of it as an imperfect, flawed structure that always begs for improvement. Such a professional must be liberally educated. This person must come to see the discipline as a human construct, a rough approximation of an ideal form. To be liberally educated is to pass through the relativizing experience taught by the skeptic, the debunker, the postmodern critical theorist, the pragmatic idealist. But the aim of this teaching is not estrangement from a discipline but an enticement to creativity within it.

(p. 128; emphasis in original)

“Passing through” may not name clearly enough how the liberal education curriculum is taught but it suggests the kind of intellectual opportunity envisioned by the Carnegie Corporation.

Liberal education is also defined in the vocabularies of institutions, colleges and universities themselves, and organizations acting as advocates for their collective purposes.
The Association of American Colleges and Universities (AAC&U), which devotes considerable resources to making the case for liberal education among its members—many of whom are former teachers’ colleges now preparing the majority of American teachers—has named these essential “outcomes”:

• Strong analytical, communication, quantitative, and information skills.
• Deep understanding of hands-on experience with the inquiry practices of disciplines that explore the natural, social, and cultural realms.
• Intercultural knowledge and collaborative problem-solving skills.
• A proactive sense of responsibility for individual, civic, and social choices.
• Habits of mind that foster integrative thinking and the ability to transfer skills and knowledge from one setting to another.

No courses or other parts of the curriculum are named, no particular kind of knowledge is specified, and the Association ignores the specific intellectual practices named by Anderson, those that might prompt disagreements among members with its endorsement of “relativizing.” As an important contribution to the recent history of liberal education reveals (Orrill, 1995), the conflicting premises, goals, and practices even among those in and out of the mainstream disciplines of the arts and sciences—favoring increased attention and support for liberal education makes such curricular pieties inevitable.

The vocabulary of the AAC&U definition, in its attention to pluralism and social responsibility, reflects shared goals with teacher education (as it does with many other forms of university-based professional education), or the view that teachers are “change agents” and teaching is an activity aimed primarily at achieving social justice. But critics of teacher education, including those who find teachers “miseducated,” often lament that the part of liberal education focused on “important issues” and the “intellectual world,” are of less interest to teacher educators who cannot see very far beyond their own professional interests and the conventions of progressive pedagogy and curriculum development (Hirsch, 1996; Ravitch, 2000; Mason, 2000).

Specifying what a liberally educated teacher would know and be able to do is also difficult because of the different ways that teacher education units organize their work. These include all of the types of four year institutions, from the small liberal arts college to the large research university. The majority of teachers are educated at regional “comprehensive” universities (in the Carnegie classification) where vocationalism usually dominates liberal education. As their statements of mission and curriculum reveal, most pledge loyalty to the kind of liberal education defined by the AAC&U. The problem, of course, characteristic of large institutions with many purposes and kinds of students, is to identify how such ideals are made part of professional education and practice. Given the variety of forms of teacher education, reflecting institutional differences (Howey and Zimpher, 1989), liberal education can hardly be the prescriptive activity its traditional partisans desire. In fact, as Paul Dressel (1954) noted during another reform period, “One great difficulty is that the ideal of a liberal education untainted by vocationalism exists more in the imagination of conservatives than in the reality of the past” (p. 291).

**Custom and ruin**

Bruner’s questions about the aims of the curriculum are late twentieth-century ones. What answers does the history of liberal education offer? According to Carnochan’s account,
one of the best, “The aggregation of practices sanctioned by custom, and incorporating the multiplicity of purposes embedded in the idea of liberal education, has made it next to impossible to think matters back to the beginning” (Carnochan, p. 119). Even so, he works his way back from a curricular episode in the Culture Wars of the 1990s to present a familiar sequence of events, now characterized as a “long term struggle of contested ideas,” or more dramatically as a “battleground.” The determining nineteenth-century U.S. engagement (a version of earlier ones in England) began when Harvard President Charles Eliot, thinking he was strengthening institutional and student responsibility, replaced the prescribed curriculum with the elective system. A key rationale was Eliot’s belief that his initiative would yield the self-reliance necessary in a democracy with a changing and fast growing economy. But Eliot’s move was challenged by other influential leaders (like President McGosh of Princeton) and the disagreement prefigured episodes of reform and, inevitably, more disagreement for decades.

Without degree requirements (or with minimal ones) the developing American university could respond to the rapid growth of knowledge in old and new disciplines and expand its sponsorship of science and scholarship. The new curriculum, if it could be called that, also prompted individual responsibility among students whose choices, ideally at least, reflected judgments about what was most important to know. According to Eliot: “That all branches of sound knowledge are of equal dignity and equal educational value for mature students is the only hopeful and tenable view in our day” (cited in Carnochan, p. 17). Eliot could be mistaken for a late twentieth-century spokesman for the proliferation of majors whose utility is wholly defined by their relation to the marketplace. But setting the limits of the new system at “sound knowledge” represented in his view the high standards that remained in the revolutionary elective-based curriculum.

The famed innovations associated with (in the 1920s) Columbia’s world civilization sequence and then (in the 1930s) Chicago’s commitment to the “Great Books” signified resistance to Eliot’s vision on behalf of faith in the long term value of required courses and what they added generally (to borrow for the moment the strategy of “general education”) to any student’s education. A degree made only of electives ultimately lost out to the intentions of liberal education represented by these programs, though the versions of them that appeared across the variety of American colleges and universities were often poor cousins of the originals. Even so, the status hierarchy of American education helped to keep the prescriptive system in place despite the lack of any empirical evidence that the required liberal education curriculum had the effects administrators and faculty thought that it did (Pascarella and Terenzini, 1991). Recently, elective freedom has returned as a popular choice, particularly at elite institutions.

By the end of the twentieth century literary critic and cultural historian Louis Menand (1997) was one of a chorus of voices breaking through key assumptions about liberal education. Speaking of the teaching of literature in such programs he said:

Where the texts are not compelled to point toward a contemporary moral, the argument is commonly made that they are being read to teach the skill of reading. But reading a literary text is a particular skill, not a generalizable one. Not everyone can do it well; it takes a lot of practice and experience to get it right; and the skill is nontransferable. Knowing how to read a poem enables people to do one thing, which is to read more poems.

(p. 9)

The last of the AAC&U’s “outcomes” for liberal education confidently assumes broad powers of “transfer.” Menand’s dismissal of such an effect stands for how little can be
said for sure about the impact of liberal education, including how it has contributed to teacher education, largely via courses in the disciplines (Floden & Meneketti, 2005).

Menand (2001) himself has proclaimed traditional liberal education to be now an artifact of the “golden age” of American higher education prior to its remaking by vocationalism (or the “Education Gospel”), particularly at the large public institutions where many teachers are trained. Other influential scholars have found it threatened as a resource for intellectual vitality by catering to students’ desires to be treated as “consumers” (Edmundson, 1997), the proliferation of electronic media (Gitlin, 1998), and management of higher education according to the practices of the corporation (Lears, 2003). And it has been declared to be “in ruins” today due to its neglect by the influential research universities, reflecting the faculty’s professional preoccupation with disciplinary specialization and indifference to undergraduates (Katz, 2005). Whatever the causes, there is simply less liberal education now, as a percentage of undergraduate instruction, than ever before in our history (Brint et al., 2005). Teacher education students, as do others in the “practical arts,” experience the change in the form of the reduction of degree requirements outside the major, as the major itself—adopting in newer fields the preference for specialization in the older ones—claims more of the total hours required for graduation. In the special case of prospective teachers there is this paradox: public skepticism about their qualifications and performance has prompted more work in an academic (as opposed to a pedagogically focused) major, typically a discipline in the liberal arts and sciences, without producing teachers who can be said to be “well educated” according to the Carnegie Corporation’s enlightened expectations. In effect, some observers find consolation in the long view. Thus, Carnochan says: “However numerous the trials of American higher education, and however unstable it may seem in the after-shocks of the nineteenth century rupture, [its] trials and instabilities . . . have given it . . . tensility and strength” (p. 5). Yet, with the triumph of the “practical arts” the strength of American higher education is being redefined. The place of liberal education throughout the undergraduate curriculum remains one of its most compelling problems. “Tensility” is presumably protection from breaking into parts. It cannot be said that teacher education and liberal education were ever fruitfully unified. Whatever can be done to move one toward the other will have to reflect historical burdens and be attentive to how much pressure the teacher education curriculum—now responding to new Federal initiatives, demographic change, impending teacher shortages, and the fiscal uncertainties of the public schools—can bear from one more necessary reform.

THE LEARNED PROFESSIONS AND TEACHERS’ KNOWLEDGE

All American teachers have some experience of liberal education, but it has not counted for very much in their self-images or society’s regard for them. For, every effort to improve teaching and the social standing of teachers reflects the problem of professionalism. Teachers and their advocates have struggled for more than a century to gain recognition as genuine professionals, having authority over their work and in the community commanded by doctors, lawyers, and others.

The practice of expert pedagogy has always been seen as the central element of the claim for teaching as a “major” profession, together with knowledge of school subjects and, ideally, of child and adolescent development. Thus, for most of the past century the question “What do teachers know?” was answered with a version of the straightforward response, “How to teach.” Teachers themselves will claim that much of what they know about teaching derives from classroom experience. But that has never satisfied critics and
skeptics in the post World War Two decades from focusing on the flaws of teacher education. Thus, for them, the “miseducation” of teachers, largely according to progressive principles, has long been an obstacle to reform (e.g. Kramer, 1991). Arthur Bestor (1953), whose well known case for liberal education derived from his frustration with the consequences of progressive ideas in the administration of schools, also found teachers wanting in intellectual capacity—a reflection of what was asked of them by anti-intellectual teacher educators.

In fact, as Lee Shulman (1998) reminds us, Dewey’s vision of progressivism, still the dominant ideology in colleges of education, included the preparation of teachers in academic subjects in the form of liberal education. It reflected his commitment to the ethos of the emerging American research university, and new roles for research and theoretical inquiry. By late in the twentieth century, as higher education diversified and became more and more vocational (e.g. in the form of the “minor professions” [Glazer, 1974]), resistance to this ideal had become common. The appeal of practice obscured what could be learned from “theory,” or any subject not perceived by students as practical, in this case prospective teachers expecting a curriculum focused on methods of teaching.

Thus, Shulman registers what he believes teacher education shares with other true professions, including those based on what are called the “practical arts”

We who have tried to educate future professionals understand the challenge that is created when one’s starting point for an education in a learned profession is immersion in vast bodies of academic knowledge. We prepare professionals in universities because we make the strong claim that these are learned professions and that academic knowledge is absolutely essential to their performance.

(p. 517; emphasis in the original)

Shulman welcomes Dewey’s insistence on the value of liberal education as a prerequisite for the study of teaching but can only ask, before going on to matters of practice: “What are the liberal arts and sciences per se whose grasp would identify an individual as ‘educated’ or ‘learned’ and therefore entitled to pursue a learned profession?” (p. 518).

By the end of his account of professionalism and the education of teachers, Shulman appears to find at least as much value in “situated practice” as a resource for becoming a teacher than anything deriving from liberal education, or the benefits of study outside the immediate interests of teacher education programs. But he does not give up on it. It was Dewey’s own situation as he gained academic influence, Shulman proposes, that made him emphasize the kind of liberal education that could be provided by the new research oriented universities eager to control professional education. “While he was certainly justified in valuing a more rigorous, skeptical, and investigation-based foundation for the professions, he gave inadequate attention to the need to nurture such activities and perspectives within the communities of the professions themselves” (Shulman, 1998, p. 524; emphasis added).

Thus, in the late 1980s, with pressure for educational reform from the inflammatory national report A Nation at Risk (1983), and the problems of maintaining belief in the authority in the academic disciplines deriving from the advent of the Culture Wars, Shulman himself devised the theory of “Pedagogical Content Knowledge” as a way to consolidate subject matter learning—allied as it is with liberal education—with the practice and knowledge of teaching. “Pedagogical content knowledge,” he declared, “is the category most likely to distinguish the understanding of the content specialist from that of the pedagogue” (Shulman, 1987, p. 8). But it was also to represent what teachers knew of the “sources” of the “content” of teaching. Thus, “The teacher must have not only
depth of understanding with respect to the particular subjects taught but also a **broad liberal education that serves as a framework for old learning and as a facilitator for new understanding**” (p. 9; emphasis added).

Presumably, the “broad liberal education” would come from the teacher education student’s experience in the institution’s prescribed liberal or general education curriculum. In effect, Shulman was enlisting the entire faculty in teacher education, a familiar gesture for overcoming any “miseducation.” Indeed, as he says later in his essay, “The emphasis on the integral relationships between teaching and the scholarly domains of the liberal arts makes clear that teacher education is the responsibility of the entire university, not the schools or departments of education alone” (p. 20). An important book (Clifford & Guthrie, 1988) had advised against regarding such a view as much more than a slogan but Shulman’s confidence reflects that of his allies in the Holmes Group (1988) and other reform activities of the time aimed at strengthening campus relations between education and the liberal arts (e.g. “Project 30,” a Carnegie Corporation project of the 1990s).

There were (and are) of course, some leaders of colleges of education who were eager to guard what they perceived as their “unique” mission. Recognizing the appeal of arguments for better curricular integration and fresh academic alliances prompted one to bemoan the fact that “the historical vulnerability of teacher education has once again induced sycophantic gesturing toward the liberal arts” (Gore, 1987, p. 2). But interest in fortifying liberal education across the increasingly popular professional curriculum was a key theme in Ernest Boyer’s comprehensive and widely cited study of undergraduate education. He identified the predominant mood in this remark by a freshman: “This year I have all these ‘general education’ courses to complete. I wish I could concentrate on what I really need to get a job” (Boyer, 1987, p. 84). Even so, like Shulman, Boyer found a resource for optimism, admiring the “longing among undergraduates for a more coherent view of knowledge” (p. 85).

Shulman could not, it turns out, speak on behalf of his liberal education colleagues for what it was exactly that they would contribute to the “knowledge base” for teaching. “We may be able to offer a compelling argument for the broad outlines and categories of the knowledge base for teaching. It will, however, become abundantly clear that much, if not most, of the proposed knowledge base remains to be discovered, invented, and refined” (Shulman, 1987, p. 12). His “New Reform,” supported at last by dedication to subject matter, provided just the right setting for specification of the contributions of liberal education to teacher education which would, ideally, be woven into what teachers come to know from their encounters with educational “theory.”

But since the 1980s no such account of the distinctive professional knowledge of teaching has established itself definitively in teacher education, though Shulman’s formulation of “pedagogical content knowledge” continues to prompt considerations of the problems and possibilities of achieving one (Segall, 2004). As Mary Kennedy (1999) has demonstrated, the question of the kind of knowledge necessary for teaching will not yield to a simple dichotomy of “expert” and “craft” knowledge (or what others often call “theory” and “experience”). In her view there is a third form of knowledge mediating the two—“expertise”—that is the actual domain of teacher education. In this way she invites a fresh contribution from liberal education which can be at once propositional as in “expert” knowledge and particular as in what is known from the practice of a “craft.” It can contribute to “expertise,” in Kennedy’s terms, or to “creativity within a discipline” outside the liberal arts and sciences in the formulation (above) of Charles Anderson. New accounts of what teachers know and how they come to know it may follow from inquiries into mature cognition and the social conditions of epistemology. And scholars
of teacher education, seeking to theorize the consequences of emerging conditions of schooling (e.g. more standardized testing and pressure on the qualifications of teachers), will likely seek to explain how teachers knowledge and beliefs are changing accordingly.

“GOOD ENOUGH” LIBERAL EDUCATION

What can we do now? What form of liberal education would be of most value to teacher education and, according to Shulman and others, give it more intellectual authority and durability? Presumably, it would be the one that has been shown to be the most effective—if we only knew enough to make such a judgment. Psychologist David Winters (with colleagues) acknowledged twenty five years ago that “It is sobering to realize that we have little firm evidence one way or the other about the actual effects of liberal arts education, this most enduring and expensive Western educational ideal” (Winter et al., 1981, p. 9). And, Ernest Pascarella, who has helped us to learn a good deal about the general effects of undergraduate learning (Pascarella & Terenzini, 1991), asserted recently that “there is little evidence of [liberal education’s] long term impact” (cited in Blaich et al., 2004, p. 7).

Winters focused on the small and selective liberal arts college to demonstrate the value of liberal education. He looked also at a regional university (and former teachers college) where he found that despite having learning goals influenced by liberal education, its actual curriculum and impact on students turned out to embody the “practical, utilitarian tradition.” There is little reason to assume that things are any different today at the institutions training most American teachers. Since the early 1980s, there is only scant evidence of the impact of liberal education on any form of professional education though there have been well organized efforts aimed at just such a goal (e.g. Stark & Lowther, 1989). However, the status of liberal education in the professions, including the “minor” ones other than teacher education, remains high, as is demonstrated by their wish to claim a share in the goals of liberal learning (e.g. Flanagan, 2000; Durden, 2003; Hermann, 2004).

Historian David Labaree (2004) has proposed these alternatives for teacher education. It can either rely on the academic disciplines to provide liberal education, or, in excessive dedication to its role in training for teaching “actually displace and discount the liberal learning” students bring to their more specialized pre-professional studies (p. 105). Labaree believes that “teacher educators have neither the time nor the academic expertise to give students a deep understanding of individual subjects, much less a broad understanding of culture, language, history, and theory” (p. 105). There is, in other words, according to Labaree, little to draw on in teacher education itself to meet Carnegie’s high standard for “educated” teachers. But surely there is enough for a selective effort based largely on the current curriculum and adjusted for a small group of themes central to liberal education, or a path other than (on Labaree’s terms) deference or dismissal.

Taking my cue from Shulman’s reformulation of Dewey, I propose below potential elements of an effort to strengthen liberal education within teacher education. Liberal education of this kind is, admittedly, some distance from “golden age” versions of it. It cannot be based on any “canon,” prescribed courses, or a list of necessary dispositions, but it can represent intellectual opportunities that would “liberate” teacher education students from the limits of merely (or mainly) the professionalism of the “practical arts.” In any case, as noted by Paul Dressel in the 1950s (above), nostalgia for liberal education can obscure the fact that it only approximated what its most passionate advocates believed about its influence on students.
It is worth potential misunderstanding—and misunderstanding compounded when the context is status conscious teacher education—to refer to the results of such an effort as “good enough” liberal education. Wendy Luttrell (2000), borrowing from the psychoanalyst Donald Winnicott, adapted that phrase to explain her approach to ethnography. He had argued that the “perfect mother” is only a fantasy of childhood and that efforts to attain “perfection” distracted from recognition of the inevitability and value of “good enough” mothering, which is what most children actually get. Thus, “good enough” liberal education refers to what is possible within a professional curriculum and what can, given the abilities, interests, and willingness of the faculty, express selectively how the teacher education curriculum can be deepened from within, or as part of the work that teacher educators already do. Here are four proposals presented as contributions from prominent scholars in liberal education who are also sympathetic to the goals of teacher education.

The clueless, the cultivated, and the uses of argument

The history of liberal education is a record of competing interests and ideas. But it is only rarely that students understand the disagreements behind any particular curriculum, or any clash of ideas or theories in a discipline, or any dispute over the interpretation of a text, idea, event, or work of art. Accordingly, Gerald Graff (1992), the literary critic and historian of English as a discipline, proposed that we “teach the conflicts” in order to move “beyond the culture wars” and toward a timely pedagogy for liberal education. While this approach has had an uneven history (see Symposium, 2003) it might still be usefully applied to the teacher education curriculum as it is taught, particularly by faculty members, as I suggest in a later section, willing to see value in the arguments of opponents of the progressive ideology of pedagogy.

Unlike many scholars who turn to problems of education, Graff has given priority to practical matters of teaching and learning, making the perspective of the typical undergraduate student—generally bewildered by the interests of the faculty—a position from which to suggest reform. He refined his views in Clueless in Academe (2004), suggesting that students’ “cluelessness,” if not quite a badge of academic honor, was still an innocent sign of the inability or unwillingness of the faculty to teach what is needed before anything else in liberal education. That is, students must learn the rudiments of argument, how ideas are expressed in serious “conversation,” or the discourses of the academic disciplines. Graff believes in the capacity of all students to mount prose arguments: “[They] can argue competently when there is a real conversation that requires [them] to be persuasive” (p. 155).

Clueless in Academe is part argument itself (about the border of academic and popular communications) and part primer on the tasks of student writers. Throughout there is a focus on writing as participation in a “conversation,” or the role in any text of views and voices other than the author’s. Graff urges student writers to recognize the opposition for the contributions it makes to any argument.

[П]lanting a naysayer in your text, a move in which you deliberately make trouble for yourself, is likely to seem counterintuitive if you have been socialized to think of school as a place you get through by staying out of trouble. The five paragraph theme and other typical assignments reinforce this view by influencing students to think of writing (and academic study generally) as a business of stringing together true statements, statements that can’t be challenged. Teachers need to help students see why this apparent common sense is not only misleading, but a sure-fire recipe for
dull writing and student boredom. Unless we produce some problem, trouble or instability, we have no excuse for writing at all.

Graff’s general method (he does not of course claim it is original), the oldest of liberal education’s conventions, used in “liberating” students from their habits of thinking, is formulated as a pedagogy available to anyone who assigns student papers, including of course teacher educators.

Philosopher Martha Nussbaum also encourages better undergraduate education in making arguments but it is part of an inclusive view of the “abilities” reflected in the thinking and action of an educated teacher or any other liberally educated person. In her learned but accessible “classical defense” of reform in liberal education, Nussbaum (1997) favors the Greek and Roman Stoics who believed, again, that education properly “liberates the mind from the bondage of habit and custom.” For her, liberal education is “cultivation of the whole human being for the functions of citizenship and life generally.” In her combined representation of the origins of the endeavor, and the recent efforts at institutions of different kinds to renew liberal education according to freshly conceived purposes, Nussbaum identifies three primary “abilities” as the core of liberal education needed in all fields of higher education, including the ability to critically examine oneself and one’s own traditions, or the habit of questioning all beliefs and accepting only those that meet the demand for arguments and explanations.

For each of the abilities Nussbaum identifies a pattern of Stoic thought and action standing behind it and anticipating our interests and problems. The present, and the curriculum she proposes, can be seen as continuous with the past directly and practically, even in the maxims she favors from Marcus Aurelius, particularly one that might be a motto for liberal education: “Generally, one must learn many things before one can judge another’s action with understanding” (Meditations, 11.18, cited in Nussbaum, 1997, p. 63). While proponents of liberal education still rely on its role in “liberating” students, Nussbaum sees beyond the slogan to the productive constraints that come from educated abilities. Thus, she says,

Reason . . . constructs the personality in a very deep way, shaping its motivations as well as its logic. Argument doesn’t just provide students with reasons for doing thus and so; it also helps to make them more likely to act in certain ways, on the basis of certain motives . . . [It] produces people who are responsible for themselves, people whose reasoning and emotion are under their own control.

Nussbaum acknowledges the limits of her approach, it largely neglects the sciences, as does Graff’s, even if argument is essential to scientific inquiry. The arguments that interest him most are the ones new and intellectually inexperienced students can learn to make as they prepare for work in the disciplines, or of professional programs like teacher education. Nussbaum’s approach is conveniently complementary, focused as it is on how teaching and learning the “abilities” that “liberalize,” as her examples from different kinds of institutions is meant to show, can be woven into virtually any instructional program.

Like their colleagues in other fields, teacher educators wish for students who can write with skill and pleasure. But the problem of “arguments” is compounded by a classroom ethos reflecting the relativizing habits of progressivism and the priority it gives to “experience.” At the same time, as “writing across the curriculum” projects have demon-
Our talk, our texts, our terms

If the goals and organization of writing is recognized as an essential and realizable goal of liberal education in teacher education then inevitably attention to language itself can be made part of the curriculum. The goal would be, as Orwell (1950) put it in his famous essay “Politics and the English Language,” to make visible to students the dangers of their “half conscious belief that language is a natural growth and not an instrument which we shape for our own purposes.” Orwell was primarily interested in the “decadence” of contemporary language, its imprecision and careless reliance on overused metaphors, obscure terms, and slogans. He believed that language was concealing as much as it was expressing and that inattention to precise meanings and accessible syntax (if not outright deceit) could be cured with “conscious action.” Orwell’s essay has become a staple of liberal education, a sign of its expressive goals and the uses today of his insistence that “To think clearly is a necessary first step toward political regeneration.”

Where would such a project begin in teacher education? Historian Peter Stearns (2004), who has been a leading figure in the organization of the history curriculum in the schools, has urged for some time that “cultural analysis” be placed at the center of liberal education since it contributes “a way of thinking about aspects of human and social behaviors that shows the culturally contingent underpinnings of many qualities often regarded as fixed and immutable” (p. 10). He recognizes too that “culture,” is one of the most widely used, complex and demanding of terms in education and other fields. Thus, an influential trend in intellectual life, the “cultural turn,” multiplied the problems as well as the prospects of “culture” as the key term in guiding research and teaching. However far they might come in “cultural analysis,” the term “culture” itself is essential to education. Bruner, for example, says that “Education is a major embodiment of a culture’s way of life, not just preparation for it,” and in The Culture of Education (1996) he finds several meanings of “culture,” just as culture quite variably guides us toward the meanings we find in education and in living.

It was the history of the term “culture” that prompted the British scholar (of several fields) Raymond Williams to codify his practice of a new form of historical semantics. The result was Keywords: A Vocabulary of Culture and Society (1976; Rev. ed. 1985; see also Bennet et al., 2005) which represents a fundamental activity of liberal education, gaining understanding of the operations of particular terms in the making of knowledge and social relations. Williams recognized that what makes it so difficult to work straightforwardly with the key terms in our talk and writing was that “the problem of a term’s meaning is inextricably bound up with the problems it is used to discuss” (p. 15). What issues and problems are “inside” our most widely used terms, Williams asked, and what does the difficulty in defining many of them tell us about our experience?

Student authors and their teachers more attentive to the making and uses of arguments will make language itself a subject of teacher education. The well known “linguistic turn” that came to the humanities and some sectors of the social sciences in the last decades of the past century urged the study of discourse for knowledge of how the world
is produced, or how language represents the history of human experience as a competition of interests as well as a desire for solidarity. Professional vocabularies became the subject of scrutiny, particularly in the academic movement known as “Rhetoric of Inquiry” (Nelson, 1987). In his account of “Standards,” for example, Williams notes how “an authoritative example of correctness” became associated with “a concept of graded progress within a hierarchy.” Since then “standards” has been used commonly as both an ordinary plural term and as a plural singular. Thus, “it is often impossible . . . to disagree with some assertion of ‘standards’ without appearing to disagree with the very idea of quality.” The case is further complicated by our derogatory use of “standardization” alongside our laudatory use of “standards.” Pedagogical exploration of such a paradox, a model exercise in liberal education, can derive from the study of almost any keyword. In any language, Williams says, “and especially in periods of change, a necessary confidence and concern for clarity can quickly become brittle, if the questions involved are not faced” (p. 16).

The “interrogation” of our terms, to borrow a popular term of postmodern discourse, must be seen as steady and often slow work. No single exercise, or social history of any particular word, will transform the intellectual habits of prospective teachers. What matters in assimilating liberal education to teacher education in this instructional format is a stance or attitude toward language that makes students historians and critics of their own discourse. If, as Graff claims (and Nussbaum implies) education in any academic field means entering a particular “argument culture,” then there is a complementary “vocabulary culture” as well, or agreement among the culture’s “natives” to use words in certain ways. But habit can be the enemy of clarity or even honesty—and slogans abound in teacher education. Ethnography is familiar enough to teacher educators to offer an image of empathic but still critical inquiry in the undergraduate classroom. Education’s “keywords” are a platform from liberal education precisely because so many are rarely scrutinized for what they reveal about the fate of ideas subordinated to contemporary styles progressive pedagogy.

**Teachers as users and critics of technology**

The student arguments that Graff and Nussbaum hope for reflect the print world in which they were educated. But as they were writing their books—no doubt on computers—the foundations of literacy were being altered by the new information and communications technologies. We have access today to more resources for learning—liberal and practical—than ever before. But as is often pointed out, information is not the same thing as knowledge, a lesson in liberal education to be learned with increasing urgency in the Age of the Internet. It is one that classicist and former technology administer James O’Donnell (1998) features in his historical account of those “avatars” of oral and written language that have transformed the ways we use and think about both.

Information and Communication Technology (ICT) is still a new enough phenomenon that its novelty can obscure how fundamentally it will change our habits of literacy and learning. But it will soon be taken for granted, as it should be, and teacher education students can then pay attention to the best ways to use it and to the consequences of doing so. For technologies are not neutral instruments for teaching and learning, as we are reminded by O’Donnell and philosophers of education in the vanguard of understanding and capitalizing on new opportunities: “The capacity for transformation is not intrinsic to the technology itself” (Burbules & Callister, 2000, p. 7). The key is a relational view of ICT, thus,
Tools may have certain intended uses and purposes, but they frequently acquire new, unexpected uses and have new, unexpected effects . . . [W]e never simply use tools, without the tools also “using” us. We never use technologies to change our surroundings without being changed ourselves, sometimes in recognized, sometimes in entirely unrecognized and unexpected ways. The relationship with technology is not just one way and instrumental, but two way.

Building the classroom “identities” of prospective teachers is a favored strategy of teacher education but no working psychology will now be complete without attention to the impact of ICT on how we think about professional roles. Teacher education students have a large stake—as students and then as teachers—in guiding their own students in the uses of ICT as well as contributing to their understanding of what its uses mean for learning and living. The strategy favored in teacher education has been to study the new classroom technologies for the ways they can be used in projects of learning. But what of the social and educational practices that derive from the adoption of ICT? These are new problems for liberal education as they are for teacher education. They direct us, for example, to the nature of texts and textuality. The terms “Hypertext” and “Hypermedia” are widely used but poorly understood as signs of what digitalization invites us to do as writers and readers. As users of the Internet we have an allied critical obligation. Thus, to be “literate” on the Web means to have powers of discrimination suitable for making durable educational uses of its abundant resources.

Liberal education has always struggled with what to make of the expansion of knowledge in the disciplines and the increasing difficulty in gaining an integrative perspective. The Internet, with its rapid access to every kind of knowledge, magnifies this dilemma and especially so for teachers hoping to make their students lifelong learners. We see frequent calls for “digital” or “silicon” literacy (Gilster, 1997; Snyder, 2002; Kelly, 2003), perhaps qualifying as another “ability” to be represented in any “new” liberal education. Certainly it is in the interests of technology’s enthusiasts to identify the newest part of the curriculum with the oldest. Innovation is made safe by association. Thus,

Information literacy should in fact be conceived more broadly as a new liberal art that extends from knowing how to use computers and access information to critical reflection on the nature of information itself, its technical infrastructure, and its social, cultural, and even philosophical context and impact—as essential to the mental framework of the educated information-age citizen as the trivium of basic liberal arts was to the educated person in medieval society.

(Shapiro & Hughes, 1996)

The practical value of “information literacy” is plain, for example in understanding what it means to use a library in both old and new ways. But it would remain the task of teacher educators to make their students adept in the new ICT, just as they themselves adapt to what can be called the new “scholarly literacy” reflecting the influence of digitalization on academic work (e.g. Bell, 2005).

In the same way that liberal education has always included attention to the meanings of civic life, of living and working in groups, knowledgeable and thoughtful use of ICT requires understanding of how the phrase “virtual community” signifies new forms of electronic communication and of how people work and live together. It resembles other spaces for learning in their good and bad effects. Accordingly, a critical user of the new technology would be someone alert to how the host of new terms associated with...
ICT (e.g., the “Information Society,” “surfing the Web,” etc.) represent a complex metaphorical effort to characterize and control the new digital environment, sometimes for purposes inconsistent with liberal education and the mission of teacher education (Meyer, 2005). Teachers will use this language as much or more than any other professional group and they should be equipped to do so as critics who, in their interactions with students, illuminate the meanings of new technology as they use it. All teacher education courses using technology—and soon there will be few that don’t—should contribute to students’ growth as critics as well as users, or for mastery of “educational technology” in the spirit of liberal education.

A via media for foundations of education

It was only a few years ago that the phrase “cultural literacy” appeared as often as “information literacy” in accounts of what needed attention in education. The new information and communications technologies swept over American higher education just as the most important trend of the late twentieth century—the Culture Wars—appeared to be losing some of its force. But a generation of teachers has been educated during the Culture Wars and teaching will continue to show the effects of public disputes over what belongs in the curriculum (Hunter, 1991) and the results of widespread and politically partisan censorship of textbooks (Ravitch, 2003).

Prospective teachers often encounter the “foundations of education” in attention to the history and social relations of schooling, sometimes in encounters (typically via textbooks) with history’s most influential philosophers of teaching and learning. As such, foundations can be understood to be an extension of liberal education, or perhaps in some cases a surrogate for it in the teacher education curriculum. In the late 1980s a group of scholars in foundations did in fact propose that teacher education was a form of liberal education. They argued that “the practice of teaching should be taken as a central object of liberal study and liberal study should be taken as the object of teaching” (Beyer et al., 1989, p. 14). Their program, however, is cast in the vocabulary of postmodernism and the wish to overturn what is foundational (if you will) about the disciplines of the arts and sciences. Thus, they urge that teacher education join in the movement to “deflect rationality from its Enlightenment trajectory” (p. 103). This is a betrayal of liberal education rather than a case for it.

A recent guide to the field of “foundations” offers scholars speaking with virtually a single political voice. “It is now common,” we are told, “for teacher education programs to focus on social justice across the curriculum. It is widely understood that schools will tend to reproduce the divisions of race, class, and gender unless teachers are explicitly taught to challenge oppressive assumptions and behaviors” (Martusewicz and Edmundson, 2005, p. 76). Another contribution puts the assumptions this way: “[A]s foundationists we are working to widen the reach of justice . . . Our schools are ideal locations to conduct such an enterprise . . . and the social foundations classroom sets the path for prospective teachers to embark on that journey” (Edmundson & Bushnell Greiner, 2005, p. 153).

There is of course always the need for more justice in education and all other social institutions. But how that might come about is a question that cannot be fully answered if “social reproduction” is named as the only, or even primary, activity of schooling and the task of prospective teachers who pass unenlightened through teacher education programs. “Foundations” is essential to any effort in teacher education in the direction of liberal education if reflection on habits of thinking is to include attention to tradition as well as transformation.
The situation of philosophers of education is symptomatic, caught as they are between contrary professional identifications and practices, and the uncertain status of liberal education in the teacher education curriculum. According to Christopher Higgins (2000), “We would seem to be unique insofar as we speak a philosophical language to an educational audience, or bring philosophical tools to educational problems. The problem is that we are able to reach our educational audience only in inverse proportion to how well we speak philosophy’s strange tongue, and the problems that plague education do not strike most people as the type to admit philosophical solution” (p. 275). He acknowledges the “waning of the metaphor of philosophical foundations.” Even so, and echoing Graff, he proposes that “What teachers need is [an] invitation to be intellectuals themselves.”

Higgins would accomplish this by capitalizing on educational philosophy as a “paradigm of liberal teacher education.” This would come about by recognizing in philosophy essential questions of the ends and means of human development central to teaching: “What is human nature? What constitutes human flourishing? What facilitates growth for beings like us toward that which is good for us” (p. 278). Philosophers of education bring to teacher education their “love” of such questions and invite prospective teachers into the “conversation” of liberal learning based on “the historically removed, humanistic texts which maintain, in their treatment of questions of human becoming, an untimely relation to the present’s foreclosed and shrunken questions.” In effect, a liberally educated teacher would redirect some part of political activism toward intellectual curiosity. “It encourages them to be more circumspect about the social fabric they have been enlisted to renew, and, at the same time, to convert from a practice that runs on the fast burning fuel of altruism to the sustainable commitment of an ongoing apprenticeship to questions worth loving” (p. 280).

I find this a most timely and salutary proposal, aimed as it is at the insistence in schools of education on a role for schooling, and thus for aspiring teachers, in transformational social reform. Henry Giroux (1992) and others working in “critical theory” want teachers to be “public intellectuals” but he can only advocate liberal education for what it contributes to “a curriculum committed to reclaiming higher education as an agency of social justice and critical democracy and to developing forms of pedagogy that affirm and engage the often-silenced voices of subordinate groups” (p. 124). “Foundations” has new work to do in modifying the activist ideology of teacher education enough to make the conflict between tradition and transformation more than a location for the display of the progressive virtues of teacher educators. Thus, the social and political relations of education might be represented by the “via media” proposed by political theorist Jean Bethke Elshtain (1997). Like her heroes Jane Addams and Camus, she has little patience with comfortable theorists of injustice and recommends the via media not as a “tepid compromise” but as a form of intellectual pluralism and realism. “We arrive at democracy and our understanding of education in our own way, framed within a horizon of limited, not limitless possibility dictated by our historic time and place” (p. 363). She urges criticism of “tradition” and recognition that education is always “political” because it “is never outside a world of which politics—how human beings govern and order a way of life in common—is a necessary feature” (p. 365). But the “middle way” is the “rare but now and then attainable fruit of the democratic imagination” (p. 371).
CONCLUSION: TEACHER EDUCATION AND THE INTELLECTUAL LIVES OF TEACHERS

“Good enough” liberal education refers to opportunities for teacher education to enhance its curriculum from within by complementing professional preparation (or the “practical arts”) with attention to themes representing the liberal arts in old and new ways. In the reforms Shulman proposes he assumes there to be the necessary curricular leadership and classroom talent among the teacher education faculty. But teacher educators, often associated with the anti-intellectual legacy of educational “progressivism,” can be said to work in the university as “aliens,” perceived as “marginal” to its primary purposes (Labaree, 2004). These are not promising positions from which to advance liberal education and the commitment to academic tradition it requires. Indeed, even a sympathetic portrait of teacher educators includes the disappointing news that hardly any of the professors interviewed could respond concretely to a question asking that they name books they would have their students read so as to “make them better teachers and better people.” One confessed that “Provincialism is probably the central problem in teacher education” (Ducharme, 1980). Perhaps that is why Eliot Eisner (1995) underlined the fact that teacher education provides little more than an initiation into teaching, the only hope, presumably, for better educated teachers being in what they learn as classroom professionals.

The abundance of research in education, most of it the product of faculty in colleges of education, has not led to widespread confidence that it plays a key role in improving schools or learning. Nor does it provide images of teaching that reflect its intellectual responsibilities rather than its pedagogical and social ones. In effect, scholarly teacher educators can behave as yet another group of faculty members indifferent to the shared purposes of the university and of liberal education, with the advantage of having no apparent curricular responsibility for it either. That is what lies behind the Carnegie Corporation’s intended intervention based on a lofty intellectual standard for a career in teaching.

It remains to ask if teacher educators can in fact move their curriculum toward liberal education. Current commitments and habits suggest not, or at least that it can only be done with extensive re-education and re-thinking of the position of teacher education in higher education. But anyone who believes in lifelong learning and the change that can accompany it, as all scholars must, should be able to master what is needed to contribute. And some teacher educators already make one or more of the approaches I have named part of their teaching, though likely without identifying it—to themselves or their students—as liberal education. It is not, in any case, a matter of specialists in math or science education, for example, taking responsibility for knowledge of literary history. In the approaches to liberal education I have named, it is not new fields of learning that matter but how teacher educators position what they already know—with resources (as in what is offered by Graff, Nussbaum and others) aimed at those scholars inclined to give themselves a role in major curricular [problems] of their time, and ones that also have considerable social significance. What does Marilyn Cochran-Smith (2005) mean when she refers to teacher educators as “public intellectuals” if they can not be asked to do so?

Those teacher educators who enlist in such an effort would benefit from institutional activities in colleges of education that make visible the significance of liberal education for prospective teachers—and for their students. In his first reform manifesto, Gerald Graff (1992) smartly noted that not every new idea or method needed to be organized as a course, presenting as that would problems for an already crowded curriculum. Instead, reforms can be built into existing courses and be represented in the curriculum
by guest speakers, workshops, small-scale conferences (some combining courses for joint purposes), and other occasions for introducing new ideas to students and faculty alike.

I do not think that the attitudes Labaree (and others) identify—a measure of anti-intellectualism in colleges of education and resentment over the fact that teacher educators have any place at all in academic culture—will change soon. There are many critics of the schools, like Leon Botstein, who plead for greater regard for teachers and the abandonment of pedagogy as an undergraduate subject of study. And claims for introducing liberal education into the teacher education curriculum would no doubt be greeted with skepticism by departments believing it to be their peculiar role by virtue of their more cosmopolitan academic practices. But if it is done well, liberal education in teacher education would signify, in an unlikely corner of academic life, willingness to address a serious problem facing all institutions. Taking the high road is no guarantee of collegiate success and individual rewards. But it is consistent with the long time self-image of teacher education as vanguard project, in this case mobilizing its own curriculum for the purpose of deepening the intellectual lives of teachers.

There is frequent recognition of teaching as a peculiarly complex activity and of the demands placed on teacher education, named as an “impossible role” itself requiring new ways of understanding its possibilities and limits (Ben-Peretz, 2001). Thus, the durability of the problem of the teacher education curriculum, and fitting it to social and demographic change and to the purposes of both undergraduate education and professional practice. Even successful programs can produce what Arthur Powell calls “passive achievement,” signifying the narrowing of school reform to “measured student achievement” (reflecting primary interest in economic and vocational goals) and the neglect of lasting habits of mind. “Few educators in the elementary-secondary sector have been seriously concerned about passive achievement and the resulting weak dispersion of enduring intellectual interests in the population” (Powell, p. 15).

A version of this view might be applied to higher education and the gap between teacher education and liberal education. Powell specifies institutionally the problem Botstein had named socially and culturally, suggesting that teaching, and I would add teacher education, is the place to inspire “enduring intellectual interests.” However new definitions of liberal education adjust the role of the “canon” and study of the past, and promote instead skills or service, there is always the hope that students will have the advantage of such interests over the course of their careers—and rectify the pattern of relations between educational generations identified by Botstein and Powell. Working within teacher education to move it toward liberal education is a pragmatic strategy for adding to what is necessarily practical in the minds of students learning to teach.

The role of teacher education courses in teaching by second nature

Frank B. Murray
University of Delaware

The argument against professional teacher education courses is rooted in the undeniable fact that teaching is a naturally occurring human behavior, a wholly natural act that is an enduring and universal feature of the repertoire of human behaviors. We are, in other words, a teaching species, a species whose young cannot, and do not, survive unless they are taught, invariably by persons with no formal schooling in teaching or in teacher education. Some have argued (e.g. Gilbert & Borish, 1997) that teaching is so basic to life that it can be found at the cellular level, but most researchers find that teaching is a constellation of distinctly human behaviors that entails an intention to teach, an awareness and ascription of a knowledge differential between the student and teacher, and the teacher’s implicit theory of the student’s mind (Strauss & Ziv, 2004; Premack & Premack, 1996). Even when teaching is taken to have occurred merely when an “activity is performed that imparts information to another that would not be obtained through the normal performance of the activity alone,” there are few documented cases of teaching in non-humans (Visalberghi & Fragaszy, 1996, p. 286).

With regard to humans, Ashley and Tomasello (1998) found evidence of teaching in children as young as three years old, and Strauss et al. (2002) found that children’s style of teaching a new board game or building something changed from demonstration and modeling at 3–4 years to predominately verbal explaining at five and six years. Seven year olds can adapt their teaching on occasion to their perception of their pupil’s proficiency and knowledge. They also introduce the new teaching strategy of asking the learners if they understood, and they then adapt their teaching to the learners’ mistakes. Children’s pedagogy is also influenced by schooling itself. Maynard (2004) found that older Mayan children (6–11 years), who had been to school, were also able to adopt “school-like” teaching with their younger siblings (didactic teaching at a distance) in place of indigenous teaching practices used in families for cooking and weaving (close-up interactive demonstrations).

FEATURES OF NATURAL TEACHING

J. M. Stephens (1967) cataloged the features of naturally occurring teaching in his theory of spontaneous schooling. His argument was that schooling, a feature of all known anthropological groups, was dependent on a set of natural human tendencies that some persons had in greater degrees than others. Those who had these tendencies in generous proportions would be seen, whether they intended to teach or not, as teachers by the members of their communities. Teaching and learning would take place naturally, spontaneously, non-deliberatively, and not necessarily with any particular motive or intention to benefit the pupil. They would occur merely because the tendencies, which
fundamentally serve only the teacher’s needs, led incidentally and inevitably to learning in those persons in the teacher’s company. Teaching, in other words, was natural and spontaneous; it occurred whenever a person with these tendencies was with any other person for a protracted period, and it occurred to satisfy some need of the teacher, not some need of the student.

The particular tendencies, which sustain natural teaching and schooling, were thought by Stephens to occur in two categories—manipulative and communicative:

**Spontaneous manipulative tendency**

1. A tendency in all people to collect and manipulate things, classify them, dwell on them, play with simple and basic ideas, and create systems for grouping things—all done with no immediate tangible payoff.

**Spontaneous communicative tendencies**

2. A tendency of a person to talk about what he or she knows because an unshared experience is painful and a burden that must be eased through telling.

3. A tendency to applaud, commend, and to correct and disapprove others’ performance, but not with any motive to making them better persons. An error, for example—whether in a book or spoken on television—is spontaneously corrected even when the correction cannot possibly affect or benefit the author, publisher, or actor.

4. A tendency to supply an answer that someone else is groping for, not to help the person exactly, but to meet one’s own need to provide the answer and to fill the void of silence. (This deeply rooted tendency is perhaps why *wait time* must be a learned and practiced skill in teacher education programs so that waiting for the answer *can be done by second nature*.)

5. A tendency to “point the moral,” to show others how things are related, to show that *x* leads to *y* as in “I told you that would happen.”

The theory of spontaneous schooling, incidentally, is meant to account for two pervasive, and otherwise unexplained, findings in the research literature on schooling—(1) the universality and constancy of schooling, and (2) the fact that educational research overwhelmingly finds insignificant and small differences between educational treatments. The theory accounts for universality by arguing that wherever there are people, there are these five spontaneous tendencies, and in whomever these reside, there will be a teacher—whether in a formal school or outside one. The features of schooling, in other words, can be parsimoniously derived from the spontaneous tendencies.

The pervasive no difference findings in educational research are explained as the natural outcome of the fact that the tendencies were operating in both the treatment and control groups (e.g. in large and small classes, in computer-assisted and conventional instruction, in mixed and segregated ability groups, in classrooms with textbooks *A* and *B*, and so forth). The tendencies, by themselves, caused powerful learning effects that swamped any differential effects that could be attributed to the researcher’s treatment. These effects were explained adequately by the prevailing large scale learning theories because the spontaneous tendencies forged the defining stimulus-response learning link. They caused the stimulus to be presented, they permitted the opportunity to respond to it, and they rewarded and shaped the listener’s response to the stimulus. At the time, these conditions were thought to be the sufficient for all school learning.

The theory, like other socio-biological theories, provides a convenient base for arguing
that knowledge of subject matter, derived from the manipulative tendencies, and in the company of the communicative tendencies will outfit a person as a teacher, especially in situations where the teacher and the pupil are a lot like each other and share common goals—as they are in families and other anthropological groups. It is not important that Stephen’s speculations on the specific character of the natural or spontaneous tendencies are correct in every detail, but only that there are natural teaching abilities and that these seem to be adequate for most contemporary teaching and schooling.

The question of the moment is whether university- and college-based teacher education courses, coming on the scene in the late 1800s, offer anything that can take novices much beyond the natural teaching skills possessed by all persons, including children.

Education Life (New York Times, July 31, 2005), to take only a recent example, makes a case that teachers need only be well-meaning and well-informed liberal arts graduates who are willing to work in today’s schools. The natural teaching view is also reinforced by the fact that many effective private school teachers have not taken education courses, nor have professors, who were trained only to research, not teach, their subjects (Judge et al., 1994). A close look at contemporary higher education, however, might show that the educational weaknesses driving the public school reforms in the post Nation-at-risk period, now culminating in No Child Left Behind, can be seen as well in contemporary higher education (Murray, 1985), but the point is that university professors meet their teaching responsibilities satisfactorily without the benefit of engaging the content of education courses.

Policy-makers raise the related question: Even if formal teacher education can refine and improve natural teaching somewhat, can the nation’s needs for teachers still be met, less expensively and adequately, by the natural teaching techniques and styles we all seem to possess?

THE MANY INADEQUACIES OF NATURAL TEACHING

The theory of spontaneous schooling, and the view of teaching that is based on it, have a number of problematical consequences for contemporary schooling because schooling now takes place on larger scales than that found in families and other anthropological groups, and because schooling increasingly takes place in circumstances where the teacher and the pupils have less and less in common. As a result, reliance on the theory of natural teaching can be expected to lead to serious pedagogical mistakes for both weak and superior students. Quite apart from the matter of scale and the degree of similarity between the teacher and the pupil, the theory promotes a direct mode of instruction that is unduly limiting in terms of modern views of cognition and cognitive development. Finally, the theory provides insufficient guidance for the solution of difficult and novel problems in schooling that go beyond the natural teacher’s exclusive reliance on “showing and telling,” the core of the natural style of teaching found in children and adults.

Low expectations

When the teacher and the pupil are not alike and when the teacher has, as a result, lower expectations for the different pupil, the natural tendencies lead to very unfortunate consequences (Brophy & Good, 1986; Evertson et al., 1985). When the teacher and the pupil have dissimilar backgrounds, we can expect the natural teaching mechanisms that support familial instruction will not operate to benefit the student.

American teachers are a relatively homogenous set of lower-middle class suburban
white women, and the American pupil is increasingly variable with regard to every demographic feature (Howe, 1990; Choy, 1993). Thus, the teacher, even if he or she were to rely exclusively on the spontaneous tendencies, would still need to come to terms with the findings in a maturing literature on sexism, racism, bilingualism, cultural, ethnic, and class diversity.

Even if the teacher had acquired this information about the diverse groups in the classroom, information alone is often an insufficient basis for overcoming the natural teaching tendencies. Even experienced teachers fail to act on relevant information in an appropriate manner. Cohen (1990), for example, reports a case of an enthusiastic teacher, Mrs. O, who believed she understood and had adopted an innovative teaching approach only to have it shown that her innovative teaching was stubbornly hobbled with traditional and natural techniques.

Natural teaching leads to a predictable number of pedagogical mistakes that novices, and regrettably some licensed teachers, make unless they also have had the opportunity to learn and practice extensively some counterintuitive and unnatural teaching techniques. For example, it is certain that the natural teacher, well-meaning and well-read with good college grades, will still make the following pedagogical mistakes with their pupils for whom they have low expectations, regardless of how benignly they came to have these expectations. They will treat these pupils not as individuals but as a group, seat them further away and outside the classroom zone of frequent teacher-pupil interaction, look at them less, ask them low-level questions, call on them less often, give them less time to respond, give them fewer hints when they are called upon, and give them less praise and more blame than other pupils. And the natural teachers will do all this out of a mistaken sense of kindness that is seemingly oblivious to the pedagogical harm their undisciplined actions have caused their pupils (Hawley & Rosenholtz, 1984; Murray, 1996).

This untrained, natural, and kind person, believing the pupil does not know very much, will not want to embarrass the pupil by calling on the pupil often, will ask appropriately easy questions when the pupil is called upon, will give fewer hints and less time when the pupil fails to respond as it would be unkind to prolong the pupil’s embarrassment and so on. The educated teacher, like all professionals, and in contrast with the spontaneous or natural teacher, must discipline many of his or her kinder instincts and implement an equitable and disciplined professional approach to bring about high levels of achievement from those pupils for whom the teacher would otherwise have low expectations (Oakes, 1985). These professional actions are frequently counterintuitive and as a result require extensive practice so that they can be performed by second nature.

Higher-order forms of learning

Kantor and Lowe (2004) argue persuasively that historically the schools, with a few exceptions that proved the rule, were inattentive to quality education and higher order subject matter understanding. Teaching was largely showing and telling coupled with rapid fire teacher questions and student recitation and memorization, all practices consonant with the natural teaching regime.

A further limitation of the natural teaching regime, apart from the harm caused to weaker pupils, is that it doesn’t take the superior pupil much beyond the kind of information that can be told and demonstrated and conforms to the stimulus-response and imitative forms of learning. While such declarative knowledge is important, the forms of knowledge that are constructed by the pupil, not merely transmitted to the pupil, are increasingly seen as key to the student’s performance at the advanced levels of
the disciplines (Murray, 1992; Ogle et al., 1991). A pupil can be told and shown, for example, that A is greater than B, and that B is also greater than C, but the knowledge that A must be greater than C, and that one could know that without ever looking directly at A and C, cannot be simply given to the pupil. Not only is A truly greater than C, but more than that, it has to be greater. The notion of necessity has its origins elsewhere. Showing and telling have not been found, except in very unusual circumstances, to be effective means of “teaching” necessity (Beilin, 1971; Murray, 1978, 1990; Smith, 1993). It is one thing to know that a statement is true, but quite another to know that it must be true. The origins of necessity, and other pivotal concepts, like irony or justice, seem to lie in dialectical instruction, which demands intellectual action on the part of the teacher and the student. While more demanding on the student, dialectic or maieutic teaching, is a less direct and more subtle form of instruction than that supported by the natural “show and tell” teaching tendencies.

The naive theory of mind

Along with the natural teaching techniques there often comes a naive and serviceable, but limited, theory of the human mind (Heider, 1958; Baldwin, 1980). The pupil’s school achievement in the naive or common sense theory is tied to four common place factors—ability, effort, task difficulty, and luck. With these four factors, the natural teacher can explain completely the pupil’s success or failure in school by attributing the level of the pupil’s work to his/her ability or effort, or to the difficulty of the school task, or to plain luck. The problem with naive theory, apart from the circularity in the four factors, is that more sophisticated theories have been developed in which it can be shown that ability, to take only one example, is not fixed or stable, and that it varies from moment to moment interactively with many other mental factors, not just the few in the naive theory (Baldwin, 1980; Murray, 1991).

Naive theories also yield such maxims as “practice makes perfect,” when it is clearer that “practice only makes tired” as it is reinforced practice that makes perfect. Moreover, these naive theories give contradictory maxims like “he who hesitates is lost” and its converse, “fools rush in where angels fear to tread.” Naive theories, to take another example, see forgetting as the inevitable decay of stored knowledge, when the educated view is that forgetting is an active thinking process of interference and reorganization (Rose, 1993).

Naive pedagogy. Natural teaching is essentially showing and telling (see Olson and Bruner 1996 for an account of folk pedagogy). Naive pedagogy is based upon a transmis-

sion of intact packets of information model of teaching. Strauss and Shilony (1994) interviewed experienced and novice science and humanities teachers about how they would teach a topic of their choosing to children of various ages (7–17 years). Both novice and experienced teachers in each discipline conceptualized teaching only as the flow of information from their heads to their pupils’ heads, acknowledging their own role was only to devise manageable and interesting ways of entry into the student’s mind so the information could be stored and anchored appropriately. The student is passive, a receptacle waiting to be filled, and if the information fails to flow to its destination, the receptacle was taken to be too small and/or the student was inattentive. Because novices and experienced teachers were indistinguishable in their responses, Strauss and Shilony attributed the teachers’ responses to their pre-training and pre-existing common sense naive views of pedagogy.

In other contexts, however, there is clear evidence that experienced teachers perform differently from novices (Berliner, 1988), but mostly in the reading of highly
contextualized cues that contribute to the smooth functioning of the class and were seemingly learned on the job. The effects of teacher training seem negligible in this area.

Austing and Pelletier (1996) catalogued the following tenets of naive pedagogy: (1) children are born with abilities and capacities that unfold linearly in time, (2) instructional sequences should match developmental sequences, (3) learning occurs sequentially within a hierarchy of skills, and (4) student errors are attributable to incomplete learning or inattention. When the pupil needs to do something, the teacher need only demonstrate or model it, and when the pupil needs to learn something, the teacher need only tell the pupil what they need to know.

On the whole, these folk or naive pedagogical techniques and beliefs frustrate modern pedagogies based on dialectic, discovery, invention and collaboration. They are also at variance with some contemporary research findings: developmental pathways, for example, are rarely linear and often show fits and starts, oscillations, and even reversals, particularly when performance is at an optimal level or when a new skill is being developed (Fischer & Bidell, 1998).

These naive views of how the mind works coupled with equally naive views about the nature of the academic subject matters as received and objective truth further limit the benefits that can be expected from nonprofessional or natural teaching (see Amsler & Stotko, 1996, for examples of the possible and legitimate variations in what constitutes correct subject matter knowledge). The naive view of subject matter also shows itself principally in the area of assessment of the student’s understanding of a subject matter.

Classroom assessment

The natural or naive teacher’s evaluation of the pupil’s correct and incorrect responses provides a telling and targeted arena for distinguishing naive and educated teachers. A pupil’s reasoning may look illogical to a naive teacher, while the educated teacher will see that the pupil’s reasoning is intact, but operating on different premises from those of the set problem. The naive teacher will be distressed when a pupil who had pluralized mouse correctly suddenly pluralizes it as mouses, while the educated teacher will see the new plural, not as an unfortunate regression, but as a positive sign of cognitive advancement in which the pupil is exhibiting a newly developed appreciation of a linguistic rule that is merely over-generalized in this instance.

Other decrements in performance may also indicate educational progress; for example, readers, as opposed to nonreaders, perform quite poorly when they are asked to identify the red color of the ink in the printed word, blue, while nonreaders have little difficulty with the task (the Stroup effect). Along similar lines, some six-year-old pupils not only maintain incorrectly that the longer row of two rows of five beans has more beans, but also maintain that the longer row must have more beans and would always have more beans. These errors occur even after the pupil has just counted the equal number of beans in each row. It happens that the error, “there must be more beans,” which seems the more serious error, is indicative of more developed reasoning than the error, “there are more beans” (Murray & Zhang, 2005). Naturally, it is very difficult for the naive or natural teacher to accept any error or poor performance as a marker of progress, yet the failure to see some errors as markers of progress is another serious pedagogical mistake that stems from the naive theory of teaching and learning (see Bruner, 1961, on creative errors).

The student’s superior performance may also be misinterpreted by the naive teacher (see Strauss & Stavy, 1982, for examples where correct performance actually rests on immature and incorrect reasoning). Murray (1990) found that young children’s success
on a developmentally advanced task was, despite the appearances, not an indication of the same level of cognitive development as older children’s success on the same task.

The teacher’s scoring rubric, by which the student’s accomplishments and progress are noted, reveals even more about the teacher’s naive theory of subject matter knowledge. If a child arrives at the correct answer to a multiplication problem through serial addition, how would the naive teacher score the response—as superior or inferior to the response of a child who arrives at an incorrect answer through multiplication? Do college students, who correctly calculate the mean, median, and mode, operate at different standards of sophistication if their reasoning is based on a calculation algorithm, a mechanical model of balance, an algebraic deduction, or a special case in the calculus? Upon what theory, and by what means, would the naive teacher determine whether some solutions are more sophisticated, elegant, significant, and so forth, than other solutions. By what criteria would the teacher even see his/her teaching as successful and/or high quality (see Fenstermacher & Richardson, 2005, on these distinctions)?

The naive or natural approaches to teaching, pedagogy, and subject matter provide misleading and limited guidance to any of these questions. More thoughtful answers require deeper study than that afforded in naive theories and regrettably in many contemporary teacher education courses.

Problems with courses in teacher education

Problems in the academic major courses

The fact that many liberal arts graduates have engaged in deeper study of their subject matter and have succeeded in meeting the expectations of the faculty in their fields of study, should not be taken as evidence that they, having taken the traditional major in a subject matter, are ready to take up work as teachers, because many of these graduates, despite their high grades, have still not mastered many of the fundamental ideas of their disciplines (McDiarmid, 1992; Tyson, 1994). Surprisingly large numbers of undergraduate majors in science and engineering, for example, are simply unable to write an equation to represent the fact that there were six times as many cows in the field as farmers. Their errors are systematic. They write the equation as 6 cows = 1 farmer, rather than correctly as 1 cow = 6 farmers. Most undergraduates, including math majors, cannot think of a real world example of the division of one fraction by another (e.g. ¼ ÷ ½). Many, in fact, get the mathematics wrong in this school problem and give examples of “1¾ ÷ 2,” not “½” (Ball, D., 1991).

The naive or educated teacher’s mistakes in subject matter knowledge and its assessment are a problem under any view of teacher employment. Additional study in the subject matter would seem the obvious remedy, and nearly every reform initiative in teacher education recommends additional and deeper subject matter preparation. The exact nature of the study, however, has been shown to be complex (Wilson et al., 2001; Rice, 2003; Floden & Meniketti, 2005). Generally more preparation in the subject, particularly mathematics, is positively related to student learning, but there are inconsistencies in which additional subject matter preparation weakens student learning in some circumstances.

The problem of abbreviated study

The research on the efficacy of pedagogical courses is weaker than that for subject matter courses, but also shows some positive association with student teaching (Rice, 2003).
The strengthening of subject matter preparation, however, often comes at the expense of pedagogical and clinical training. It is doubtful, however, that a sufficient level of pedagogical training can be reached in a short period. For example, on a simple reading of Skinner, as might be found in a survey course in education, prospective teachers could believe that positive reinforcement (or reward) is an effective and preferred way to increase the likelihood of desirable pupil behavior. Without an awareness of the important exceptions and qualifications in which rewards actually weaken a response (the overjustification phenomenon), teachers will make mistakes by implementing procedures that run counter to their intentions (Cameron & Pierce, 1994).  

Similarly, upon a quick reading, the prospective teacher could come to believe that student grades should be normally distributed or that reliability is a property of a test rather than a property of those who took the test. These professional lessons cannot be easily abridged or rushed because many educational innovations are counterintuitive and subtly tied to hidden factors. For example, it makes a difference whether addition problems, like 8 + 5 = _, are presented horizontally or vertically. While a seven-year-old child, to take another example, may understand that the amount of clay in a ball would be unaffected if the ball were flattened into a pancake, she would more than likely believe incorrectly that the same pancake would weigh more and take up less space, despite the fact that the child had claimed the ball and pancake have the same amount of clay. Furthermore, it is now acknowledged that many research findings are inherently provisional and must be qualified by context and the cohort or generation of subjects who participated in the study, as different results are obtained from different cohorts and contexts on such basic questions as whether intellectual performance decreases after a certain age. Thus, having studied the research literature at one time is not a guarantee that the results can be applied at a later time with regard to such nagging and recurring issues as social promotion, skipping grades, ability grouping, optimal class size, delayed instruction, and so forth. Current and deeper study is required throughout the teaching career.

The problem of insufficient time

Sudden or effortless changes in behavior are taken by developmental psychologists as a sign that the change was not fundamental, but rather a temporary change, caused by a peripheral mechanism (e.g. fatigue, inattention, misperception, etc.), and not authentic. Protracted and extended practice and experience is needed to overcome the acquisitions of a prior stage of development or of the naive or natural teaching regime, which seems to be deeply rooted in behavior.

Smith (1989) has shown that highly motivated, knowledgeable, and experienced teachers were still unsure and shaky after ten months of practice in their efforts to implement a conceptual change science teaching technique, even though they practiced the new technique extensively under ideal teacher education conditions (extended coaching one on one). Such protracted experience is rarely afforded in the traditional teacher education course. Despite having practiced the technique in a variety of settings, having video and stimulated recall analysis of their teaching performance, and having personal feedback of their efforts, the teachers regressed to their earlier teaching style whenever the lesson took an unusual and unexpected turn (Smith & Neale, 1990). Their regression to show and tell sometimes undermined the entire point of the science lesson and science itself, because the teachers would deny or ignore an unexpected outcome in a science demonstration in favor of the outcome that was supposed to have happened. In a light and shadow lesson, when a single shadow was expected and predicted, but a double
shadow appeared, the teacher would deny it or ignore it and continue with the demonstration as if the single predicted and expected shadow had appeared, all in opposition to the new teaching technique and the tenets of science.

The classic defense against this kind of regression under stress to the more primitive and older strategies is over-learning or practice well beyond what is needed to simply learn the new skill or approach. Regrettably, few teacher education programs make the necessary provisions for over-learning.

The problem of backward design

Teacher education programs are remarkably the same in their four part format across the country—(1) general/liberal arts courses, (2) subject matter courses, (3) pedagogical or methods courses and (4) clinical experience courses. It is the substance of the courses, not the format, which varies so widely that Shulman (2005) argues that there really isn’t any teacher education curriculum in the United States. The problem is that the curricular content that is in place, varied as it is, is typically not clearly connected to the educational needs of children and adolescents. The content needs to be backwardly designed from the needs of children to the program’s content. These needs, of course, should be the driving principle in the design of teacher education courses, but the influence of other factors is more clearly seen (Gardner, 1991).

The overriding question, whose answer legitimizes any course content, is—can the content be connected, on some line of reasoning, to the teacher’s response to an educational need the child or adolescent truly has? The more distant the connection, the less convincing the course content is to the candidates and the public. The more distant the connection to the child’s needs, the less university-based teacher education is actually warranted because naive or natural teaching would be adequate, because it primarily serves the needs of the teacher, not the pupil’s.

Educational scholarship is also not currently organized around the needs of children and adolescents, but rather around the professor’s needs as expressed in the academic disciplines, the separate clinical methods, clinical practice and the norms of higher education. Were educational scholarship organized around children’s needs and the teacher’s responses to them, prospective teachers would be guided by the view that the curriculum must be shaped so that it actually solves a problem the student has. The teacher’s art is in organizing the activities of the classroom so that the student’s academic work solves a genuine problem the student brings to the classroom. As it is now, students work on problems that others have brought to the classroom, problems imposed by the school and largely artificial, viz., the student has to avoid school failure by taking actions that meet the teacher’s expectations no matter how unrelated they are to anything the student directly cares about. To connect the curriculum to problems students truly have is an exceptionally demanding task for the teacher, which is another reason why teachers need more than their natural teaching skills. Natural teaching, at least as Stephens set it out, is organized solely around the teacher’s needs and flows from innate dispositions the teacher has.

Olson and Bruner (1996) conclude that the shift from the simplest pedagogies of natural teaching to the more sophisticated ones available in scholarship entails a focus on what the student, not the teacher can do, on what the student thinks, on the student’s view of teaching itself, and on knowledge as an emergent event in the dialectic between the teacher and the student.
The problem of failed confidence in quality assurance

Ironically, the teaching education program is held back by the very fact that teaching has all the attributes of the other professions—accreditation, professional associations, standardized tests, licenses and credentials, advanced degrees, and so forth. Teachers, since the end of the Second World War, have been required to have college degrees (in some cases, graduate degrees), pass standardized examinations, meet state license standards, fulfill the school district’s requirements for tenure, complete annual update courses and show other evidence of professional growth. While there is some fragile evidence for the efficacy of the license in the teaching field and advanced degrees (Rice, 2003), none of these requirements, all demanding in their appearance, has credibility within or outside the profession as each is routinely waived when there are shortages of otherwise qualified persons for the public schools. In the case of the private schools, many states typically set and require no standards at all, a practice that only reinforces the lack of standing the current standards have.

To take one example of the low regard in which these bureaucratic standards are held, the National Board for Professional Teaching Standards (NBPTS), departing from the practice of other professional national boards, elected not to require a degree in teacher education, a state teaching license, or study at an accredited institution for those permitted to sit for its certification examinations. National Board certification, itself, is not even required for advancement in the field or promotion to higher levels of professional responsibility.

None of the standards for teaching, collectively or separately, apparently provides the public any assurance that the teacher is competent. Few feel the nation is at risk over these lax professional standards because, sadly, the naive view of teaching is held by large numbers of policy-makers and the public. Yet, many feel the nation is still at risk, and it is largely over the fact that neither today’s graduates nor their teachers seem to understand very much of what they have learned.

Going beyond natural teaching

While there are the many weaknesses in the naive approach to teaching, a strong case for professional education courses is also difficult to make owing to the failure of educational scholarship and teacher education to coalesce around any powerful and generative theory of schooling and teaching (Shulman, 2005). Although it is unfortunately a negative example, one test of the tentative and embryonic nature of educational scholarship in this regard is that there is still no consensus among educational scholars and practitioners about what would constitute educational malpractice (Collis, 1990).

Apart from teachers’ acts that are expressly illegal, there is surprisingly no accepted view, except in a few extreme instances (like no longer forcing lefthanders to switch hands for penmanship), about what educational practices should never be employed in classrooms. Even competing practices, like whole word and phonics instruction in initial reading methods, have reasonable levels of current scholarly support and adherents. Without a sure sense of what constitutes educational malpractice, teaching and teacher education are behind other professions, which have fairly well-articulated codes of good practice, and which by extension define malpractice as the failure to follow good practice (see Cochran-Smith, 2005, for an argument that teacher education is still somewhat ahead of other professional fields in demonstrating its effectiveness).
Challenges for educational scholarship

On the whole, the accumulated record of educational scholarship has not yet yielded a coherent academic discipline of teacher education (Cochran-Smith & Zeichner, 2005). Until the last three decades, scholarship in education relied heavily upon findings from other disciplines, particularly the behavioral sciences. The transfer of those findings, collected in non-school settings, to issues of educational practice has been generally unsatisfying. Within the last thirty years, however, the powerful methodologies of other disciplines have been turned on classrooms themselves with the result that life in classrooms has been studied in such a way that some fairly convincing and counterintuitive conclusions about schooling rise to level of the standards of a university course.

Even though there are significant gaps in it, over the last thirty years, a body of scholarly literature has developed that supports the teacher’s reasoning about some educational practices and allows the teacher to evaluate the merits of some educational innovations, techniques, and policies. This literature does provide sound advice about some matters, such as whether a teacher should adopt ita (the initial teaching alphabet) that regularizes spelling by having 44 letters, one for each of the phonemes of English. The argument is that ita facilitates early reading by reducing the discrepancies between English orthography and pronunciation. The teacher who had studied Osgood’s transfer surface, unlike the thousands of teachers in the USA and Britain who adopted the innovation in the 1970s or in the 1860s (when the innovation was called phonotaby), would know what the likely benefits to reading and harm to spelling of the innovation.

Similarly there is a substantial literature on the controversial question of whether failing pupils should repeat a grade or be socially promoted to the next grade, or whether a gifted pupil should skip a grade, enter school early, be grouped separately from less gifted pupils. How could the natural teacher decide whether or not pupils should use calculators in their arithmetic lessons and homework? How can the naive teacher avoid making mistakes in answering questions like these unless they study the relevant scholarly literature on these matters, and in the cases where the literature is unhelpful or absent, unless they have also acquired ways of thinking and inquiring about their own teaching?

Despite these fragmentary examples of useful scholarship, the lack of an encompassing, systematic and authoritative body of scholarly knowledge about teaching, let alone about the education of teachers, presents a formidable obstacle to the study of teaching earning a place in the college curriculum and to teaching becoming the genuine profession it aspires to be (Cochran-Smith & Zeichner, 2005). Cochran-Smith (2006) poses a more expansive list of unanswered questions about teaching that would also take the prospective teacher well-beyond answers that could be derived from natural teaching, an apprenticeship in the school, or the study of current scholarship about teaching. Much fundamental work needs to be done, including an enlarged view of what constitutes scholarly evidence.

The challenge of education as a university subject

Owing to the natural teaching skills, it is possible to perform many routine teaching tasks without the benefit of experience and great theoretical sophistication, but errors of judgment multiply when events in the classroom are not routine and when past practice is an insufficient guide. The question is how to provide the aspiring teacher with a way of thinking and a set of skills that will take the new teacher beyond the ancient skills of natural teaching that are proving to be insufficient for the challenges of contemporary schooling.
Teacher education courses, however, are probably not warranted at the university level if the teacher is held only to the standard of presenting material truthfully and clearly, to giving students an opportunity to practice, and to testing the student’s grasp of the material (teach, test, hope for the best). Teacher education is also probably not warranted at the university level if the needed ways of thinking and skills can be acquired in an apprenticeship during an internship in a school. It is discipline based scholarship that informs practice and leads to the practitioner’s understanding of practice that uniquely commends teacher education as a college or university course of study.

The modern teacher’s obligation is at a high level. It is not enough to have today’s students simply learn the subject matter; they must understand it (Gardner, 1991). On this argument the teacher’s own education must have the same attributes as their future students. Understanding, it would appear, cannot be produced by didactic telling, or by showing and coaching, although the pupil may learn and remember what the teacher said and may imitate what the teacher did. Understanding seems to be dependent upon the student’s active investigation and experimentation, guided by dialectic—the teacher’s skillful questioning and conversation aimed at the student’s misconceptions and provoking the student to resolve discrepancy—forging, thereby, a coherent understanding of the events at hand. Unlike solutions that are learned, the dialectical outcomes are personal and extraordinarily resistant to forgetting.

Neither pupils, nor teacher education candidates, will understand their lessons if the teacher’s or professor’s role is merely to deliver information and imitate action. While dialectic requires the pupil to do something overtly—to speak, respond, and question—there are other features of teaching for understanding that require the teacher to abandon the naive and spontaneous techniques as the prime teaching style in which the teacher is more active than the students.

Modern views of intelligence and cognition, for example, are clear that knowing is negotiated, distributed, situated, constructed, developmental, and affective—all features of knowing that entail greater degrees of student action than is found in natural teaching. As Olson and Bruner (1996) put it

truths are the product of evidence, argument, and construction rather than holding by dint of authority whether textual or pedagogic. The model of education is dialectical, more concerned with interpretation and understanding, than in the achievement of factual knowledge or skilled performance.

(p. 19)

The challenge of the content for pedagogy courses

Of course, the first challenge for university courses in teacher education is to address the weaknesses and inadequacies in natural teaching. This is not an easy problem to solve because many of the documented weaknesses associated with natural teaching were found not only in novices but in experienced teachers, who, even though they had taken many traditional education courses, apparently regressed to the natural teaching techniques under the pressure of teaching.

All teachers know that the subject matter they teach is inevitably different from the subject matter they learned from their professors. The teacher must transform the subject matter into something else—a teachable subject that has its own structure and logic and is something that will make sense to the pupil. The question is: what body of scholarship guides the teacher in selecting an appropriate logic and structure? The knowledge that supports this conversion of the storehouse of knowledge into the school curriculum, into
something that has meaning for the pupil, is sometimes called, *pedagogical content knowledge*, and ought to be the unique and signature content of the modern education course (see Murray, 1991, for an account of various structures available for the content of a teacher education program in elementary education).

The specification of pedagogical content knowledge entails the appropriate ways of organizing information and knowledge. It is the search for structures, ways of representing the subject matter, analogies and metaphors, that will take each pupil well beyond what can be held together temporally and spatially through rote memorization. Pedagogical content knowledge is fundamentally about those structures that confer some appropriate level of understanding, and it is ultimately about those structures that actually advance understanding.

Discussions of pedagogical content knowledge are at the heart of university and college pedagogy courses. *Hamlet* will at some point be taught (Grossman, 1990), but how should it be represented, and what should teachers claim it is about—the use of language to talk about language, the pathology of indecision, the unconscious mind of the adolescent, the re-creation of an historical event, or something else? How is the teacher candidate to think about these questions and who can best guide the candidate to compelling answers?

Some structures are merely scaffolds, and as scaffolds they are provisional and designed solely to advance the pupil to another place. Thus, it may be appropriate to introduce the 1812 Overture, and by implication all classical music, as the re-creation of an event, as programme music, in which the two national anthems battle each other in the overture as the armies did on the battlefield. But, then again, this may not be an appropriate scaffold. This representation, or structure, which is hopelessly inadequate for any later understanding of musical composition, may engage and propel the student to further study, or it may provide a distorting foundation for later study. How is the naive teacher to know?

In teaching *Huckleberry Finn*, the teacher inevitably interprets the book as a story of gender and race relations, or generation gaps, or a historical period, or latent homosexuality on the frontier, or injustice, and so on (Graff & Phelan, 1995). Science teachers often attempt to clarify the nature of electric current by comparing it to the behavior of water currents in various sized pipes, or they compare the circulation of blood to the circulation of hot and cold home heating system, and so forth. Is this a good way to think about electricity or arterial circulation? How would the naive teacher or apprentice know? The answer to the question is not to be found in physics, biology, or in education, but in a qualitatively different kind of knowledge that comes from a new academic discipline of education built on inquiry by disciplinarians and pedagogues. This knowledge—the knowledge of what is a telling example, a good analogy, a provocative question, a compelling theme—is a proper object of study and could yield a deep and generative understanding of the disciplines. To have multiple ways of representing a subject matter, to have more than one example or metaphor, to have more than one mode of explanation requires a high order and demanding form of subject matter understanding.

In the teaching of descriptive statistics, for example, it may make sense to introduce the notions of central tendency and variation with physical models of equilibrium, or with computer graphics representations of data points, or as calculation formulae, or as the solution to certain questions in the behavioral sciences, or as derivations of algebraic equations, or as part of a system of expressions in calculus or some other branch of mathematics. These pedagogical options merit academic study by an approach that is as serious as the approach to any question in any academic discipline.
Few have seen that this kind of knowledge advances the academic discipline itself. At the cutting edge of a discipline, pedagogical content knowledge and theoretical breakthrough may be the same thing. What happens on the frontiers of a discipline? The researchers invent ways to communicate with each other about the phenomenon under study; they invent ways to make sense of the phenomenon. The “double helix,” for example, was as much pedagogical content knowledge as a Nobel Prize winning description because it provided a means for researchers to teach each other, to converse about the genetic code.

When the teacher invents a structure that organizes and gives meaning to a field of study, he or she is doing exactly what the scholar or researcher does when the scholar provides a novel or generative structure for his or her peers about some problem in their field. Thus, the study of pedagogical content knowledge can be a study on the cutting edge of a field, insofar as new modes of representing the subject matter and new ways of making it interesting and meaningful are formulated.

The challenge in designing contemporary pedagogy courses also entails the incorporation of other information that also has not traditionally been part of them (see Murray, 1991). By way of somewhat lengthy example of this kind of information, consider what a teacher would need to know about physics and the student to teach the concept of weight. The young child can be shown to operate with the following “system” for weight (Murray & Johnson, 1970, 1975): Weight for the pupil in the early grades can be shown to be a function of the following aspects of an object:

1. The object’s mass, with additions of mass yielding greater weight, etc. and no change in mass yielding no change in weight.
2. Size, with larger objects weighing more, etc.
3. Shape, with some shapes weighing more and some less (e.g. flattening increases weight).
4. Texture, with the rougher weighing more and the smoother weighing less.
5. Temperature, with the colder weighing more and the warmer weighing less.
6. Hardness, with the harder weighing more and the softer weighing less.
7. Continuity, with whole weighing more than the sum of the components.
8. Label, with the object labeled, bigger, weighing more than the object labeled, smaller.

Some factors that are potential members of the system can be shown to have no influence on the child’s physics of weight of an object; for example,

1. Object’s horizontal position, with an object weighing the same at either end of the table.
2. Object’s vertical position, with an object weighing the same in deep hole or at the top of the tallest mountain.

The young child’s view of weight is based upon a consistent child-logic in which the factors above influence weight lawfully and dependably (Murray, 1982; Murray & Markessini, 1982). Adolescents and many adults operate with the following simpler and to some degree more sophisticated “system”: Weight is a function of only the object’s mass, the only influential factor to survive the child’s system. In other words, the only way adults can think of to change an object’s weight is to alter its mass, that is, add something or take something away from the object. The young child can imagine many
other ways for altering weight, all unfortunately incorrect, however reasonable they seem to the child (and as it happens, to some adults on some occasions). The educated person operates within another system of the following factors organized as a mathematical expression of the product of the first two factors below divided by the square of the third:

1. Mass of the object (as above).
2. Mass of the planet (the largest nearest object), with larger planets yielding increased weight.
3. The distance between the centers of the above two factors, with weight decreasing with increases in the distance. In addition the educated person may be able to convert the expression into a genuine equation via a value, \( g \), for the gravitational constant which permits algebraic manipulation of the terms in the expression.

At this point other factors may be introduced into the expression to treat certain buoyant forces or variations in the earth’s \( g \), etc. After lengthy further education, gravitation is seen as an aspect of a space-time continuum in relativity physics and weight can only be determined once the time and space frame of the object is determined (as the weight of an object that is falling in space).

There is a similar developmental progression for the child’s understanding of the beam balance in which the young child’s understanding of “weighing” is controlled solely by the effects of adding or subtracting weight from a beam balance pan without regard to the influence of any other factor (Siegler, 1981). Later the distance of the balance pan from the fulcrum is gradually factored into the child’s scheme for the operation of the balance, and after several more developmental steps we see the product moment law in place in the adolescent’s thinking.

Similar scholarship exists for other concepts and relationships in the school curriculum. The information, unlike much of the current teacher education curriculum, has face validity because it contains precisely the kinds of information that prospective teachers readily accept as clearly relevant for their future work. It is also the kind of information that would not be found in an apprenticeship approach to teacher education. It is the kind of information at a university standard that also supports the teacher who holds a developmentally appropriate perspective on instruction.

Conclusion
The skepticism and cynicism that accompanies contemporary university-based teacher education courses is rooted in the fact that some forms of teaching are natural human behaviors that seem deeply rooted in our species. However, the forms of teaching we seem to have by nature are largely limited to showing and telling and are most effective only when the teacher and the student share common cultural assumptions and goals. These natural forms of teaching, however, are less effective, and on occasion even harmful, when the goals of education go beyond the kind of information and understanding that cannot be simply imitated and copied.

If the goals of schooling are restricted to what can be imitated and copied, then teacher education as a university subject is probably not warranted as the natural and spontaneous teaching regime can be relied on to accomplish the school’s mission. If the goal of teacher education is to merely have persons who can teach by performing new techniques by second nature, teacher education as a university subject is probably not warranted either. If the goal, however, is to have teachers who can understand their practice and inquire into
its purpose and efficacy, then the study of teaching practice, based upon scholarship and scholarly investigation, warrants space in the higher education curriculum. Regrettably, many of today’s education courses are weak because they are not organized around the pupil’s educational needs or the newer scholarship about the development of the student understanding of the concepts in the curriculum. They also devote insufficient time to the candidate’s unlearning some of the limiting aspects of natural teaching before supplanting them with the newer pedagogical techniques.

The remedy for advancing beyond natural teaching and the weaknesses in today’s education courses, however, is not to abandon the courses in pedagogy, the hallmark of any genuine profession of teaching, but to strengthen these courses along the lines advocated by an array of reform groups, inside and outside the education schools. These reforms all reduce to a demand for a much higher standard for the teacher’s work—namely having all their students understand the curriculum—and requiring a teacher education program that can deliver that outcome for their graduates.

NOTES

1 Draper (1976) and Konner (1976) show there are complex limits to universality of teaching in anthropological groups. In some cultures children are taught to eat but not to sit and to walk and vice versa in other cultures.

2 Prenack and Premack (1996, p. 315) point out that “pedagogy is not an official anthropological category: no catalogue lists the pedagogical practices of different groups . . . the anthropology of pedagogy is largely nonexistent; its proper study has yet to begin.”

3 See further comment on the over-justification phenomenon in the Spring, 1996 issue of the Review of Educational Research, 66, No. 1, 1–51.

REFERENCES

Murray, F. (1978) Teaching strategies and conservation training. In A. M. Lesgold, J. W. Pellegrino,

Teaching is the sort of work that both inspires and mystifies, and many people have tried to articulate the qualities they believe make someone a good teacher. Some say a good teacher is bright, others that she is caring, others something else. These speculations take on a more practical quality when the conversation turns to how to prepare good teachers, for the preparation question can lead to detailed curriculum and program specifications. So literature on the question of how to produce good teachers includes philosophical inquiries, program designs, and empirical tests of hypotheses.

Arguments about how to prepare teachers have become especially shrill in recent years, as observers become increasingly concerned about the quality of the education system as a whole. Debates have also been stimulated by a new body of work called “value-added” analyses, which examine variations among teachers’ classroom effectiveness. From these analyses, we know that teachers vary considerably in the amount their students learn, so much so that if a student had two or three consecutive weak teachers, his overall academic achievement would be seriously compromised (Aaronson et al., 2003; Rokoff, 2003; Sanders & Horn, 1998). These studies demonstrate that teachers differ substantially in their effectiveness, and raise to prominence the question of how to better prepare teachers.

The aim of this paper is to examine empirical evidence regarding the merits of the most prominent hypotheses about educational backgrounds that will improve teacher effectiveness. One hypothesis, the one that dominates most state regulations, is that teachers need specialized knowledge about issues directly pertinent to teaching—things like classroom management, techniques for teaching, the role of school in society and other educational issues. We call this hypothesis the Pedagogical Knowledge hypothesis. Virtually every state subscribes to this hypothesis by requiring prospective teachers to take courses from departments of teacher education whose mission is to prepare people specifically for teaching careers. But even though this hypothesis is widely represented in state regulations, it is not without its detractors. In particular, two other hypotheses are offered, either as alternatives or as supplements. One argues that teachers need Content Knowledge more than pedagogical knowledge. Proponents of this hypothesis frequently note that teachers cannot teach content if they do not know it. While it is possible in principle for teachers to obtain pedagogical knowledge as well as content knowledge, advocates for content knowledge frequently pit the two against one another under the assumption that courses providing pedagogical knowledge take up too much space in the college curriculum and hence remove space for courses providing content knowledge that would ultimately be more beneficial to prospective teachers. There is, among those outside the teacher education community, a general skepticism about the merit and value of courses taken in teacher education programs per se (Conant, 1963; Damerell, 1985; Hess, 2001; Kramer, 1991; Labaree, 2004; Lagemann, 1999).
In the past two decades, a third hypothesis has been put forward that suggests that teachers need a blend of pedagogical and content knowledge, something called Pedagogical Content Knowledge. This knowledge consists of such things as how students understand, or misunderstand, particular substantive ideas, how to present particular substantive ideas in a way that makes them more accessible to different types of students, or how to use particular resources in lessons about particular content. This third hypothesis, then, suggests that there is a relationship between pedagogy and content that teachers need to understand.

All of these hypotheses focus on the college curriculum, suggesting that there are particular domains of knowledge that can make a difference, and that teachers should take courses in these domains. There is another hypothesis that challenges the validity of all of these. This fourth hypothesis argues that the best teachers are bright, well-educated people who are smart enough and thoughtful enough to figure out the nuances of teaching in the process of doing it. For people subscribing to this hypothesis, the route to improving the quality of teaching lies in recruitment, not in specific courses that will prepare people for this work.

Advocates of the first hypothesis tend to acknowledge all of the rest as well. That is, they rarely argue against content knowledge, against pedagogical content knowledge, or against the value of having bright, well-educated people teaching in the nation’s classrooms (see, e.g. National Commission on Teaching and America’s Future, 1996). However, advocates for content knowledge and for bright, well-educated people often do argue against the pedagogical knowledge and against pedagogical content knowledge hypotheses. So the debate really focuses mainly on the merits of allocating college curriculum space to courses specifically about teaching and learning.

We take the view that all of these hypotheses need to be examined. Therefore, we seek evidence about all of them, rather than confining ourselves to the most controversial one. For the first three hypotheses, we examine studies of teachers’ college course-taking histories. We assume that courses in education represent pedagogical knowledge, courses in mathematics represent content knowledge, and courses in mathematics education represent pedagogical content knowledge. Because our fourth hypothesis deals more with recruitment than with college curriculum per se, we test this not by looking at studies of college courses, but instead at studies that examine the selectivity of the teachers’ alma maters.

In this investigation, we confine our inquiry to the content area of mathematics, and take student achievement in mathematics as our indicator of teachers’ effectiveness. This limitation is necessary in part to ensure that all curricular options are tested against a common outcome. We test hypotheses only about teachers’ educational background, not about their tested knowledge.

The studies reviewed here come from a larger collection of literature addressing the role of a wide range of teacher qualifications to the quality of teaching. Below we describe our search procedures for gathering this literature and discuss some of the methodological problems in this literature. We then review findings for college curricula and for recruitment.

LITERATURE SEARCH PROCEDURES

Literature for this paper was drawn from a larger literature data base gathered as part of the Teacher Qualifications and the Quality of Teaching (TQQT) study. The TQQT data base includes studies that examine the relationship between at least one teacher
qualifications and at least one indicator of the quality of teaching. Our original search criteria defined qualifications to include such aspects of teachers’ backgrounds as their college curricula, test scores, credentials, grade point averages and degrees. Indicators of teaching quality included such things as direct observation of classroom practice, student achievement, and principal ratings, as long as these indicators were obtained after the teacher had a full time teaching position.3

Excluded from this compilation were studies of student teachers, preschool teachers, and teachers of college students and adults. Also excluded were studies published prior to 1960 and studies conducted outside the United States, on the grounds that these contexts may be too different from contemporary United States to be applicable. For our tests of the four hypotheses about educational backgrounds, we also eliminate studies published before 1980, on the grounds that curricula change over time and earlier studies may no longer be applicable.

Literature was obtained by searching the Education Resource Information Center (ERIC), PsycInfo, Dissertation Abstracts International, and EconLit. Search terms included those commonly used to define either qualifications of teaching quality, such as assessment, certification, teacher education, teacher effectiveness and so forth. In addition, we searched the bibliographies of these articles as well as those of literature reviews and policy analyses in this area and searched recent issues of entire journals whose domain encompassed this area. Studies were screened to ensure that they included at least one qualification and at least one indicator of quality, and that their analysis explicitly linked the two. Links could be established with group comparisons (e.g. a group of traditionally certified teachers versus a group of alternatively certified teachers); correlations, various multivariate strategies, or through qualitative approaches. As of this writing (Summer 2006) the data base included about 480 studies. More details about the study and the data base can be found at http://www.msu.edu/~mkennedy/TQQT.

To test our four hypotheses about teachers’ educational backgrounds, we searched this literature for two types of studies. First, to test hypotheses about the college courses, we sought studies that tried to assess the relationship between the courses teachers took in college and the teachers’ current effectiveness. We sought tallies of courses taken in education, mathematics, or mathematics education. We also sought tallies of whether teachers had majored or minored in either of these subjects or held advanced degrees in them. The bright, well-educated person hypothesis cannot readily be tested by examining college curricula, but we did find two types of studies that are relevant to that hypothesis: those that measure of the status, or selectivity, of the institution which teachers had attended for their college education, and those that looked at the effectiveness of teachers who were recruited by Teach for America. Because the TFA recruits from prestigious colleges and universities (Raymond & Fletcher, 2002b), we consider these studies to be tests of the bright, well-educated person hypothesis.

Methodological issues

Research on the relative value of different kinds of teacher preparation has been impeded by some very difficult methodological problems. One problem is that many of the credentials of interest don’t really vary much. For example, the value of a bachelor’s degree would be difficult to assess in the United States because some 99 percent of teachers already have a bachelor’s degree (National Center for Education Statistics, 2003). A test of the value of this degree would require an extensive search to find teachers who lacked the degree, to serve as a comparison group for those who have it. In many important respects, the teaching population in the United States is quite homogenous, a
phenomenon that is hard to reconcile with the large differences in effectiveness that we see. For example, we know that about 75 percent of them are women and 84 percent are white (National Center for Education Statistics, 2003). We also know that 99 percent of teachers have a bachelor’s degree and that 90 percent of teachers are certified.

On the other hand, bachelor’s degrees and teaching certificates can have quite different meanings across educational institutions and across states. The United States has hundreds of institutions offering college degrees and they vary in size, quality, religious affiliation, research orientation and so forth. In addition, states have a plethora of certifications on their books, often exceeding a hundred. And they differ in the curricula they require for any given certificate (Ballou & Podgursky, 1999; Council of Chief State School Officers, 1988; Rotherman & Mead, 2003). We avoid ambiguous measures such as certification and degree level and focus instead on the number of course teachers take in particular subjects and on the selectivity of their alma mater. Of course these also can have different meanings in different places but we think their meaning is more clear than certification is. This strategy helps increase the variability in measured educational background, and at the same time improves the clarity of their meaning.

Another problem affecting all studies of qualifications is that teachers decide for themselves which qualifications they will obtain. Researchers do not randomly assign teachers to colleges or universities, nor to their college majors. Thus measurements such as the number of courses taken on topic X or Y reflect not only the knowledge teachers gained from these courses but also their initial interest in those topics. We can never separate teachers’ initial interest in a subject from the knowledge they have acquired about it. Thus, if we find that courses in a certain topic seem to lead to better-quality teaching, we cannot infer that if states require teachers to take those courses, that the same results will obtain. Only after the courses are required can we see their effect on teachers who have no interest in them. This problem plagues the present examination as much as every other examination of teachers’ qualifications. Prospective teachers take some college courses because they are required to, but they take others because they want to, and it is likely that these two reasons bear on the degree of benefit that teachers derive from their courses.

A similar self-selection phenomenon occurs when teachers seek employment, for their assignment to schools is also not at all random. In fact, there is now considerable evidence regarding the way teachers and schools become matched. We know, for instance, that most young people who choose teaching as a career are white women who come from rural and suburban communities. We also know that, upon graduation, they seek positions in schools that are similar to those they attended when they were students themselves (Boyd et al., 2003). They engage in a process of differential migration, such that college graduates who grew up in the suburbs seek teaching positions in the suburbs, and those who grew up in small towns seek teaching positions in small towns. We also know that school systems give preferences to their own graduates (Strauss, 1999), so that both schools and teachers are seeking to match each others’ cultural and demographic fundamentals. Finally, we know that urban schools, and other schools serving lower income and non-white populations, have greater difficulty filling their vacancies, have higher turnover in their teaching staffs, and are more likely to employ teachers with fewer qualifications (Boyd et al., 2002; Lankford et al., 2002; Wykoff, 2001). As a result they tend to have more novices than other schools and to have less-qualified teachers as well. These processes, taken together, suggest that the positions teachers eventually take are likely to be affinity assignments, such that their social backgrounds and their qualifications match the social backgrounds and qualifications of their students.

Now imagine how these processes influence research. We want to see if teachers with different types of qualifications have different influences on their students. But teachers
with different qualifications have already been matched to students with different qualifications, through these natural processes of differential migration and affinity assignments. One result of these processes is that the schools whose students need the most educational help—that is, those who are the least qualified as students—are allocated the least qualified teachers, while those who are the most advantaged are allocated teachers with more qualifications. If we examine a simple correlation between, say, the prestige of the teachers’ alma mater and their students’ achievement test scores, we would likely see a relationship even if the teachers have had no impact at all on their students, simply because they have been matched to their students through these processes of differential migration and affinity assignments. The migration and assignment processes make it difficult for researchers to tell whether teachers created their students’ achievement levels or whether, instead, students with different achievement levels have attracted different kinds of teachers.

We address this problem of non-random assignment by limiting our review to studies that use relatively sophisticated statistical methods. We seek studies in which researchers try to separate out these various influences statistically, by measuring all the things they expect to influence teachers’ effectiveness, and include them in a statistical model. These more sophisticated models include not only teachers’ qualifications, but also measures of students’ socio-economic status, race or ethnicity, perhaps measures of school size, finances, or demographic makeup, and perhaps other characteristics of the teachers themselves, such as their beliefs or values. In these studies, the goal is to find a relationship between teachers’ qualifications and the quality of their teaching practice after measuring and accounting for other relevant influences. They cannot guarantee that they are documenting causal influences, of course, but they are more able to measure and take into account competing explanations for their data. We also strengthen our inference by examining multiple studies, each with its own statistical model.

Finally all studies of teachers’ qualifications are complicated by numerous influences that intervene between teachers’ prior college experiences and their current teaching practices. Any given sample of teachers will include some relatively new teachers, some with a few years of experience and some with many years of experience. Many things may have influenced their teaching since they obtained their original college degrees and certifications. They may have worked in different schools, taken different kinds of professional development courses, confronted parents with different expectations for their children. Any of these experiences may have influenced their practices and their effectiveness. Yet our research is ignorant of these influences and seeks evidence of only one influence, their college education, and that may have occurred years ago. Indeed, time itself is an intervening influence, for teachers who obtained their certificates 20 years ago may have experienced very different educational programs than teachers who obtained their certificates five years ago. And studies that were published 20 years ago may have included teachers whose preparation was quite different from that of teachers prepared today (Metzger et al., 2004).

We address these problems in part by limiting ourselves to stronger research studies, studies that are more likely to have addressed these issues. We include only those studies that meet these important criteria.

1 The studies must use relatively sophisticated models, models that allow the researcher to take account of numerous other possible influences. These studies typically rely on either multiple regression or hierarchical linear models, both of which allow more opportunity than do simple correlations or group comparisons to measure additional influences and take them into account.

2 The studies must include a pretest as one of their factors. Measures of student
achievement are like snapshots taken at a specific time. They measure student knowledge at a particular time, but that knowledge reflects the sum of everything students have learned throughout their entire lives, from parents, other teachers, other adults and from each other. Moreover, they can present a relationship that reflects the effect of affinity assignments more than the effects of teachers’ influence on student learning. We therefore prefer studies that incorporate a pretest score as one of the factors in their model, or as part of a gain score. The inclusion of some measure of prior achievement enables the researcher to separate the knowledge students gained prior to studying under the teacher who is the focus of the study.

3 The studies must focus on individual students or teachers rather than institutional collections of teachers. Some researchers rely on school averages or district averages of teachers and students, rather than using data from individual teachers. Aggregated data are often used when researchers borrow data bases that belong to school districts or states. Such data bases may not include individual-level information, or may restrict access to it to protect teachers’ privacy. These aggregated data conceal all of the variations among teachers within each school or district and focus on variations among schools that may be due to many things other than instructional influences, things researchers have no knowledge of (for more on this issue, see Murnane, 1981; Hanushek et al., 1996). As a result, they may lead to erroneous estimates of the relationship between teachers’ qualifications and the quality of teaching practices. We therefore limit our attention to studies that focus on individual teachers and students.

One final note is needed about the findings we present here. A synthesis of this sort requires us not only to define our criteria for including studies, but also to define criteria for selecting specific findings from each study. Researchers frequently present multiple statistical models, each with unique features. They sometimes provide findings for multiple subgroups (e.g. high-achieving and low-achieving students) or for multiple achievement sub-tests. To avoid over-representation of any one study, we selected a single model from each grade or sample examined. Our decision rules were to first seek models that met our criteria of including a pretest and focusing in individual teachers rather than aggregations. If an author presented one model using a gain score and another using the pretest as a covariate, we chose the covariate model. We selected fixed effects over random effects. We selected total samples rather than subgroups and total test scores rather than sub-test scores. We avoided models that included interaction terms. If different models from the same sample are presented in different publications, we selected the most recent version. Otherwise we selected the model that included the largest number of curriculum measures or, absent differences in this, the one that was most complete with respect to other variables. We preferred one-year gains to two-year or partial-year gains.

Final sample

The studies we examine here represent what we consider to be the best evidence of the relationship between teachers’ qualifications and their students’ mathematics achievement. By limiting our review to these studies we gain more confidence in our findings. Our criteria have been recognized by numerous other researchers as indicators of better research designs (see, e.g. Goldhaber & Anthony, 2003; Hanushek, 1971, 1996; Murnane, 1981). In this respect, we follow Slavin’s (1984, 1986) suggestion that reviewers should focus on best evidence, and we agree with him that what constitutes best evidence depends on the research questions and contexts. Table 61.1 lists the studies that meet our criteria for best evidence.

(Continued overleaf)
DATA ANALYSIS

We have devised a novel yardstick for defining influences on student test scores. We want to see whether teachers who took more courses have students with higher achievement gains than other students. But the apparent influence of a college course will look different when student achievement is measured on a 50-point scale than when it is measured with a 10-point scale. The conventional solution to this problem is to divide all effects by the group’s standard deviation, thus creating a scale that puts all effects on a common

* Betts et al. estimates for minors are not included in this analysis.

Chiang et al. double degree is not included in Figure 4 because it confounds Bachelors degree and Masters degree.

Rowan et al. not included in Figure 4 because we could not convert the data into a gain score metric.

CK = Content Knowledge; PCK = Pedagogical Content Knowledge; PK = Pedagogical Knowledge; BWE = Bright Well-Educated.
metric. But this approach can only work when all researchers derive their standard deviations in the same way (see Hedges, 1986 for more on this). If one researcher provides a pooled within-school estimate of variation while another provides an estimate that includes between-school variation, then the standard deviations will not convert effect sizes to a comparable metric. Moreover, even if the standard deviations were comparable, we face another problem when studies rely on national data bases and their associated tests, for these tests are not aligned with local curricula. They will likely measure some content that was not taught and fail to measure some content that was taught. Because they miss some areas the teacher has influenced, and measure some areas teachers have not tried to influence, we expect these tests to underestimate teachers’ actual instructional influence on students. This is not due to inadequacies in the teacher but to a lack of alignment between the teachers’ curriculum and the test content. Hence effects based on national tests may not be comparable to effects that are based on state or local tests which are designed to reflect the local curriculum. In fact, this underestimation is apparent in the average annual gains shown in national data bases, which are often just one or two points for the entire school year.

Our solution to this “yardstick” problems is to define all outcomes relative to the average amount that students gain during a given school year. That is, instead of standardizing effects by dividing them with the standard deviation, we standardize by dividing them with the average annual gain for the population. For instance, if majoring in mathematics adds 1 point to students’ achievement scores, and if students typically gain 3 points during the year, then we would say that the effect of the major was equivalent to 1/3, or 33 percent, of students’ annual gain. Our estimates of effects, then, are based on the following equation:

$$\frac{b_i}{\bar{Y}_{post} - \bar{Y}_{pre}}$$

where $b_i$ is the unstandardized regression slope for a particular qualification taken from a particular sample; and $\bar{Y}_{post} - \bar{Y}_{pre}$ is the gain in mathematics achievement for the population from which the sample was taken.

This strategy offers certain advantages over other standardizing strategies. We do not have to eliminate studies because they calculate their standard deviations in different ways, for instance. And we do not have to worry about how closely student tests are aligned to local curricula because these are equalized by the use of average gains as our yardstick.

FINDINGS

Findings are presented in two sections. In the first, we summarize research that examines the influence of teachers’ curricula on their students’ mathematics achievement. These studies allow us to evaluate hypotheses about the relative importance of pedagogical knowledge, content knowledge, and pedagogical content knowledge. In the second section, we examine two sets of literature that are relevant to the bright, well-educated person hypothesis. These include multiple regressions that measure the status or selectivity of the institutions that teachers attended, and a handful of studies that contrast TFA teachers with other teachers.
Evidence for the influence of college courses

When people suggest that teachers need more knowledge of, say classroom management, they really mean more knowledge of this relative to other areas of knowledge. And when people argue that teachers do not need knowledge in an area, they rarely mean that this knowledge is absolutely lacking in value, but rather that it is not as valuable as some other knowledge would be. Defined in this way, the empirical question then becomes one of identifying the value added by different parts of the teachers’ total college education, where one part might be courses in education, another might be courses in subject matter (in our case, mathematics), and a third might be courses in math education, or how to teach mathematics.

Because estimates of effects can depend statistical models—that is, on the combination of other variables the researcher measure and control in their model—it is not possible to directly compare one study’s estimate of effects with another’s. We solve this problem in two ways. First, we examine studies that test more than one hypothesis within a single statistical model. These studies allow a direct comparison of different course content under the same methodological conditions. Our second strategy arrays findings from studies conducted under more varying statistical conditions. We have already made these studies somewhat more comparable by requiring that they all fall within our best-evidence boundaries. We also increase comparability by examining all effects relative to student achievement gains on that particular test.

Within-study comparisons

Here we examine two studies that meet our best-evidence standards and also test multiple hypotheses within a single study. The first (Monk, 1994) examines secondary mathematics teachers and the second (Harris and Sass, 2006) examines all grade levels of teachers.

Monk used multiple regression, a statistical technique that allows researchers to estimate the contributions of several different potential influences within a single equation. Monk’s equations included student background variables as well as several measures of teachers’ educational backgrounds. He estimated the influence of individual courses teachers took as well as the influence of majoring in mathematics. Since Monk studied both sophomores and juniors, we review two equations, one for each group. Figure 61.1 displays his findings.

Each hatch-mark in Figure 61.1 represents the amount that students’ test scores increased (or decreased) with each additional course their teachers took in math or math education, assuming that everything else that was measures is held constant. Recall that the “amount” is measured relative to the average gain for all students in the population, so it reads as a percentage of that gain. So, for example, assuming no change in students’ backgrounds and assuming no other measured differences among teachers, the top line indicates that, among teachers of sophomores, each additional course taken in math education—that is, in methods of teaching mathematics—is associated with an increase in student achievement equivalent to about 16 percent of sophomores’ average achievement gains.

The general pattern, for both sophomores and juniors, is to see the largest benefits in mathematics education courses, somewhat smaller benefits in mathematics courses, and a negative effect for majoring in mathematics. In this sample of mathematics teachers, the average teacher took about eight courses in mathematics but only two in mathematics education.

Monk suspected that there might be a pattern of diminishing returns as teachers took
more and more courses in mathematics, and tested this idea by distinguishing early course-taking from more advanced course-taking. He found that the benefits of courses in mathematics tapered off after about five courses. In Figure 61.1, the large positive effect of teachers’ college math courses for juniors represents added benefit for each of the first five courses teachers took, while the smaller number (8 percent) represents the additional benefit for each course taken beyond the first five.

The most surprising finding here is that, at both grade levels, when teachers majored in mathematics, their students actually gained less than students whose teachers did not major in mathematics—about 8 percent less for each group of students. This apparent negative result is a surprise since most of the debate about teachers’ curriculum focuses on the value of courses in education, not on courses in content knowledge. Even Monk’s diminishing returns hypothesis cannot explain this outcome.

Here we face one of the difficulties of squaring research findings with our common sense. It is hard to imagine that additional study in any topic could actually make someone a less effective teacher. The implication would be that these courses are providing harmful knowledge. We seek an alternative explanation for this pattern. Many explanations are possible, including possible flaws in the statistical model, but the one that seems most probable to us is that teachers who chose to take more courses in mathematics were already different from other college students even before they took the courses, and the difference is one that leads to less effective teaching. Perhaps college students who choose to major in mathematics have different personalities, values or beliefs that render them less effective as teachers, and it is these initial differences that explain for the apparent negative effects of additional courses, not the courses themselves. This pattern of findings reminds us of the two important interpretive difficulties in this type of research: the effects we see in these studies must be interpreted in the context of the entire statistical model, and that these measures of course-taking reflect both the knowledge gained from the courses and the teachers’ original interests and dispositions that motivated her to take these courses in the first place.

Figure 61.1 Estimates of the relationship between teachers’ college coursework and their students’ achievement gains in mathematics (from Monk, 1994).
Now let's look at the Harris and Sass (2006) study. This study is distinctive in part because it offers an unusually large collection of estimates of effects and because it is an unusually high-quality study. These authors use hierarchical linear modeling, an analytic strategy that better accommodates the nested organization of teachers and students in schools, and they also used fixed effects, a strategy that better accommodates hidden differences (such as subtle personality differences or school climate differences) among teachers and schools that might interfere with interpretations of findings. The sample for this study is limited to a single state (Florida), however, it provides great detail regarding teachers’ college coursework and the data are available for elementary, middle and secondary teachers.

Figure 61.2 shows the array of effects that Harris and Sass reported. It can be read in the same way as Figure 61.1, except that these authors examined course credits rather than courses per se. Each hatch mark represents the effect of an additional credit of study in a particular knowledge domain, measured as a percentage of students’ one-year achievement gains, again assuming all other variables in the model are held constant. The figure shows a large number of estimates because these authors were able to include multiple grade levels and to distinguish specific course content—for instance, they could separate out courses in one aspect of education versus another. Like Figure 61.1, this one suggests a great variety in size and direction of effects. As we argued when reviewing the Monk study, we are not inclined to hypothesize that knowledge itself can be harmful, and therefore suspect that the apparent negative effects shown in this chart reflect either a statistical anomaly or a pre-existing difference among teachers who chose to take different patterns of courses.

Looking first at elementary teachers, Figure 61.2 suggests that credits in education and in math education are somewhat more beneficial than credits in mathematics per se (Again we assume that negative effects do not really mean that the additional knowledge has harmful effects). However, when we examine the patterns for middle and secondary teachers, the effects are far more various and difficult to interpret. All three domains of

![Diagram showing the relationship between course credits and student achievement gains](image)

*Figure 61.2* Estimates of the relationship between course credits teachers earned in college and their students’ achievement gains in mathematics (from Harris and Sass, 2006).
knowledge show both positive and negative effects. While the math education courses tend to balance between positive and negative effects, education courses strongly lean toward negative and mathematics courses also lean slightly toward negative.

Harris and Sass did not test for the possibility of diminishing returns for courses taken in different content areas. However we may still imagine that people with different prior inclinations tended to take different patterns of courses and these prior differences could account for the patterns we see here. For instance, since the estimates within education refer to specific content (class management vs. instructional strategies, etc.) it is possible that teachers who chose these courses had prior personalities or beliefs that render them relatively more or less successful as teachers, independent of the effect of the credits per se.

**All best-evidence studies**

Our second approach to reviewing studies of teachers’ educational backgrounds gathers together all the research findings that examine courses into a single graph. Figure 61.3 summarizes all the best evidence regarding the number of courses teachers took (it does not include the Harris and Sass data since that examined course credits rather than courses per se), and Figure 61.4 summarizes all the best evidence regarding intensive study in a particular area. In these figures, each hatch mark represents one estimate from one study. Together, they represent many different populations and statistical models.

The most important reason for examining all of the studies in a single graph is to search for broad patterns of effects that may rise above the variations in statistical models and other study details. Such a pattern might give us an idea of the true relationship between teachers’ educational backgrounds and their students’ achievement, one that is not an artifact of the individual studies.

Figure 61.3 still reveals quite a variety of outcomes, though they do lean toward positive at all grade levels and subjects. However, with the exception of Monk’s findings,
most effects are relatively small. Since these hatch marks represent the effect of individual
courses, we might expect small effects which could accumulate as teachers took more
courses. As we saw in the Harris and Sass study, there does seem to be more dispersion in
effects of courses for secondary teachers than for elementary.

Figure 61.4 summarizes all estimates of the effect of obtaining a full major in either
subject, or of obtaining an advanced degree in either subject. Since these hatch-marks
represent the effects of extensive study in one of these domains, we might expect them to
be substantially larger than those of individual courses summarized in Figure 61.3.
Indeed, most of these effects are larger than those in Figure 61.3, but not by much.
Moreover, many are negative as well as large.

No researcher other than Monk has tested for the possibility of diminishing returns for
additional courses in a given subject but such a relationship might help us understand this
pattern of outcomes. For example, among elementary teachers, majoring in either educa-
tion or mathematics is apparently detrimental to student achievement, a finding that
contradicts the more generally positive pattern shown in Figure 61.3 of effects of indi-
vidual courses. Moreover, we found another negative effect of majoring in mathematics
(from Rowan et al., 2002) which we were unable to convert to our metric and so are not
displaying here. But the contradiction between the apparent benefits of individual courses
and the apparent detriment of extensive study is at least partially reconciled if we assume
that there are diminishing returns as teachers accumulate more and more courses in any
one domain. Suppose, for instance, that additional courses benefit teachers up to a specific
point, but add little or no benefit after that point. Since researchers rarely devise models
to accommodate curvilinear relationships, we might expect to see the effects of a college

* One additional study (Rowan et al., 2002) reported an achievement loss for elementary students whose
teachers were majoring in mathematics. It is not shown here because we were unable to convert the data to this
metric.
major flipping from positive to negative as different researchers use different statistical models. Or we might assume that the people who choose to major in either subject are somehow different from those who take a few courses in each area but major in neither.

Only at the level of advanced degrees do we begin to see a clear difference across domains of knowledge. Though there are fewer estimates of the effect of advanced degrees, the pattern in education clearly differs from that in mathematics. Both estimates of the effect of an advanced degree in education are negative and all three estimates of the effect of an advanced degree in mathematics are positive. We need to add one caveat to this observation: all of these estimates of the effect of advanced degrees come from a single data base, the National Educational Longitudinal Study of 1988. It is possible that these results are an anomaly unique to this data base. Ludwig and Bassie (1999) are convinced that the pretest used in this data base is not adequately controlling for non-random assignment of students to their teachers. However, if the finding is real and generalizable, it raises an important question about the value of obtaining a masters degree in education. We offer two speculations here. First, since most school districts provide salary benefits to teachers who earn advanced degrees, practicing teachers have an incentive to seek them out, and education programs may try to oblige them by offering degrees that are not very rigorous or beneficial to their teaching practice. Hence the degrees themselves may be relatively weak. Second, it is possible that the type of person who chooses to obtain an advanced degree in education differs from other teachers in being less effective to begin with and that the degree does nothing to improve their effectiveness.

Summary

In this section, we have examined evidence regarding three hypotheses about the kind of knowledge teachers need. We are interested in the relative merits of pedagogical knowledge, pedagogical content knowledge, and content knowledge. We used coursework in education to test the hypothesis that pedagogical knowledge makes a difference, coursework in mathematics education to test the hypothesis that pedagogical content knowledge makes a difference, and coursework in mathematics to test the hypothesis that content knowledge makes a difference.

Despite variability among study findings, we see some broad patterns. First, courses in all three domains of knowledge appear capable of improving elementary teachers’ effectiveness. For elementary teachers, the modal benefit of additional courses in education and in mathematics education appears to be around 0–3 percent of students’ annual achievement gains, with courses in mathematics and in mathematics education adding somewhat more than that. Second, estimates are far more variable among middle and secondary teachers than among elementary teachers, whether we are looking at individual courses or intensive study in a domain. This may be because there are more anomalies in secondary-level data bases, perhaps more confounding variables in secondary studies due to local practices of assigning students and teachers. Still we can make out some trends. In particular, the differences between Figures 61.3 and 61.4, suggest that courses in all three domains have diminishing returns, such that the effects of majors, in either education or mathematics, are highly variable but on average very close to zero. Finally, we see a clear difference between mathematics and education in the benefits of advanced degrees, and suspect this difference may be due to both the differences among teachers who choose to seek out these degrees as well as differences in the benefits of the degrees themselves.

Throughout this text we have considered a variety of hypotheses to account for the patterns we see. The hypothesis of interest, of course, is that knowledge in these domains
benefits teaching. But the presence of negative effects raises the question of whether knowledge can be detrimental to teaching. We are inclined to believe that these apparent negative effects are not due to the courses themselves, but rather to either pre-existing differences among people who chose these different curricular paths, or to statistical anomalies, perhaps resulting from the presence of curvilinear relationships or multicollinearity on the statistical models employed.

Evidence for the bright, well-educated person hypothesis

We rely on two very different types of studies to test the bright well-educated person (BWE) hypothesis. One group of studies examines the influence of the status, or selectivity, of teachers’ alma maters on their current students’ achievement. The other examines the effectiveness of teachers who were recruited into the profession via the Teach for America (TFA) program, a program that explicitly recruits people presumed to be bright and well educated, but who have not necessarily studied teaching.

Institutional status

Two studies examined indicators of institutional status, or selectivity, in their attempts to account for teacher effectiveness. They differ in how they define and measure institutional status, however, so each must be examined separately. Figure 61.5 and 61.6 show the pattern of changes in students’ mathematics achievement that are associated with the status of their teachers’ alma maters.

The first study (Clotfelter et al., 2004a, 2004b) is the only study in our data base to explicitly recognize that teachers and students may already be matched by their social class and qualifications even before any data are collected. These authors checked individual schools to see how students were assigned to teachers. They found that many schools had assignment policies that placed less advantaged students with different teachers than more advantaged students. In Figure 61.5, we see the difference in the apparent benefit of the status of teachers’ alma maters, as classified by Barrons’ College

![Figure 61.5](image-url) Relationship between the prestige of teachers’ alma maters and their students’ gains in mathematics achievement (from Clotfelter et al., 2004a, 2004b, 2006). All estimates are compared to teachers from “less competitive universities.”
Ranks, when examined with the full sample and again when examined only in those schools that relied on random assignment practices. The figure suggests that higher alma mater status is indeed associated with higher student achievement in the full sample, where students and teachers are matched, but that the opposite pattern appears when the study is restricted to schools that randomly assign students to teachers. In schools where students are not matched to their teachers, teachers from the most prestigious alma maters appear to be less able to foster learning in their fifth grade students.5

Figure 61.6 summarizes findings from the second study (Aaronson et al., 2003), which focuses on ninth grade mathematics teachers and defines institutional status with a scale based on US News and World Reports classifications. We might expect affinity assignments to be even more prevalent in secondary schools than in elementary schools, since secondary schools tend to engage in more tracking, but Aaronson and colleagues tested for this possibility by comparing their observed classroom assignments with a variety of simulated assignment possibilities. Based on these analyses, the authors argue that their data did not suggest systematic classroom sorting. With respect to outcomes, the pattern suggests that students’ mathematics achievement tests scores were usually higher when their teachers had attended higher-status institutions. But the pattern is also uneven and suggests that only the level 5 institutions stand clearly apart from the others. This may be due to unusually anomalous samples in some of the status categories. Since the first study was conducted in elementary schools and this one in secondary schools, it is possible that institutional status has a greater impact in secondary school than in elementary school.

Teach for America recruits

The second type of study that is relevant to the BWE hypothesis examines teachers who were recruited into the profession by Teach for America (TFA). On its website, TFA defines its recruitment strategy as follows:

![Secondary math teachers](image)

*Figure 61.6* Relationship between the prestige of teachers’ alma maters and their students’ gains in mathematics achievement (from Aaronson et al., 2003). All estimates are compared to teachers graduating from universities ranked by *US News and World Reports* as “other.”
Each year, Teach For America launches an aggressive effort to recruit the most outstanding graduating college seniors and recent college graduates—people who will be the future leaders in fields such as business, medicine, politics, law, journalism, education, and social policy. We seek a diverse group—socio-economically, racially, ethnically, politically, and in every other respect. We seek leaders who can describe significant past achievements and who operate with an exceptional level of personal responsibility for outcomes. Because our corps members face such tremendous challenges, we seek applicants who have demonstrated determination and persistence when confronted with obstacles in the past. Lastly, we seek people with the specific skills—from critical thinking to organizational ability—that we have seen characterize our most successful teachers.

(retrieved June 27, 2005 from http://www.teachforamerica.org/looking.html)

TFA does not assume its recruits will take up teaching for their entire careers, but does ask for a two-year commitment and most recruits apparently honor that commitment.

Once admitted into the program, TFA enrolls candidates in a 5-week summer institute that requires them to teach summer school students while concurrently taking courses in such topics as classroom management, learning theory, student diversity and so forth. To test the benefits of this program, researchers usually contrast TFA recruits with other teachers.

There is considerable muddle about what one is learning from such a comparison. Some researchers think that this comparison informs them about the value of pedagogical knowledge, assuming that the comparison group of traditionally-certified teachers has taken courses in pedagogy that TFA recruits have not taken. But TFA teachers are not completely lacking in pedagogical knowledge because TFA does provide some of this content to its teachers. In addition, TFA candidates must also meet state requirements for certification and many states require that teachers who enter the field without a traditional certificate must work toward obtaining one during their first few years of practice. In these cases, differences in pedagogical knowledge between TFA recruits may be small at the outset and may disappear completely as TFA recruits take the courses required for traditional certificate.

There is another reason why these comparisons don’t inform us about pedagogical knowledge: in the studies we review here, most teachers in the “other” category also lack a full certificate. The non-TFA teachers in these studies represent an eclectic mix of emergency-certified, alternatively-certified and traditionally-certified teachers. For all these reasons, then, contrasts of TFA teachers with other teachers are not very informative about the value of pedagogical knowledge, traditional certification, or any other aspect of teachers’ college course work. We cannot be sure how much pedagogical knowledge either group actually has.

But the contrast does inform us about the value of different recruitment strategies, since TFA focuses its recruitment on more selective institutions. So an examination of TFA graduates offers us a good opportunity to test the bright, well-educated person hypothesis in situations where pedagogical knowledge may not be substantially different.

We found three studies that meet our evidence standards and that examine the influence of TFA recruits on student math achievement scores. In each of these studies, the number of TFA teachers available for study was relatively small. The first two studies were both conducted in Houston, Texas, using data that belonged to the school district. These two studies both used multiple cohorts of teachers and students, and were not able to control students’ classroom assignments. They both used multiple regression to try to statistically adjust for other differences among students.
The first Houston study was conducted by Raymond and Fletcher (Raymond & Fletcher, 2002a, 2002b; Raymond et al., 2001). These authors used 1996–2000 data from upper elementary and middle school grade levels. During this period, Houston hired between 350 and 420 new teachers each year, but only about 20–25 per year, or less than 10 percent, were TFA teachers. The researchers note that TFA teachers were placed in schools with higher percentages of Latinos and with higher percentages of students receiving free or reduced-price lunches. Test scores were also lower in the schools where TFA teachers taught.

The second Houston study (Darling-Hammond et al., 2005a) was explicitly designed to replicate and extend the first by paying more attention to the specific credentials of the comparison group. These authors found over 100 different certification categories in Houston’s data base and, after studying the state’s code, reduced these to seven categories: standard, alternative, emergency/temporary, certified out of field, certified no test, uncertified, and unknown. Because we are interested in the TFA as a means of testing a recruitment strategy, we do not report findings from this study that address the certification value of the TFA program.7

The third study of TFA recruits was an experiment in which students within each grade level and school were randomly assigned to either a TFA teacher or another teacher (Decker et al., 2004). Because experiments entail random assignments of students to programs (in this case, to teachers with different kinds of credentials) they remove the confounding caused by affinity assignments that tends to occur in natural settings and they increase the chances of seeing an unbiased estimate of the effect of the program of interest.

Because the Decker et al. study is an experiment, it is stronger than the other two, but there are certain problems it shares with the other studies. In all three studies, the number of TFA teachers is rather small, so that researchers had to combine grade levels to obtain reasonable group sizes. And in all three studies, the non-TFA teachers represented an eclectic mix of credentials. For example, in their comparison group of novice teachers, Decker et al. found that 31 percent had a full traditional certificate, 28 percent had a temporary certificate, and another 25 percent had emergency certificates. Hence the comparison is not a good test of alternative credentials. However, the contrast remains a reasonable test of the bright, well-educated person hypothesis, since the main distinction between these two groups lies in TFAs recruitment strategies. Less than 4 percent of the novices in the Decker et al.’s “all other” group graduated from a competitive college or university, whereas 70 percent of TFA teachers graduated from such schools.

Figure 61.7 shows the effects of TFA recruits relative to other teachers in each of these three studies. Each hatch mark represents a particular estimate of the influence of TFA

![Figure 61.7](image)

*Figure 61.7* Effects on students’ achievement gains in mathematics when teachers are recruited via Teach for America Program, all studies.
recruits on their pupils’ mathematics achievement. They are all positive, ranging from 3 percent of annual growth to 21 percent. These findings are encouraging for the bright, well-educated person hypothesis, in part because we are more confident that the normal processes of differential migration and affinity matching have been disrupted in one case by an experiment and in the other two by the TFA recruitment and placement strategy. So these findings are more persuasive than those about institutional status that were displayed in Figures 61.5 and 61.6. However, the most persuasive findings, those from Decker et al., also yielded the smallest effect.

Summary

Evidence regarding the bright, well-educated person hypothesis comes both from studies of the institutional status of teachers’ alma maters and from studies of TFA, which can be considered as more of a recruitment strategy than a different approach to certification. Studies in the first group are more susceptible to biases associated with affinity assignments, but those in the second group correct for these biases by systematically drawing teachers from elite institutions and placing them in schools with less-qualified students. The second group, however, is limited to very small samples of bright, well-educated teachers which are then compared with large, amorphous samples of teachers with highly variable backgrounds. If we can assume that more selective institutions tend to produce brighter, more well-educated people, then both sets of studies provide some support for the hypothesis that bright, well-educated people do help students learn more.

For those who argue for the BWE hypothesis as an alternative to pedagogical knowledge, this evidence is reassuring but not entirely satisfying. The strongest study in our set, the experiment, suggests that bright well-educated people add about 3 or 4 percent to students’ average annual achievement gains, an amount roughly equal to the benefit of a single course in education or in mathematics education. The comparability of findings across hypotheses suggest that casting the question as one of either/or will not lead to an optimal approach to teacher education.

DISCUSSION

Since teachers are in the business of educating students, we want to believe that their own education is relevant to their effectiveness. Many researchers have tried to test the effects of teachers’ educational backgrounds on their students’ achievement and they have had to solve a wide range of methodological problems to do so. In this synthesis we have focused only on relatively high-quality studies and we have rendered their findings comparable by using average population gains in achievement as a common yardstick. Based on these studies, we suggest that individual courses do indeed add to elementary teachers’ effectiveness, and that this is true for all three domains of knowledge—mathematics, education, and mathematics education. Secondary students also benefit when their teachers have taken additional courses in mathematics and in mathematics education. However, there is reason to believe that additional courses eventually have diminishing returns, so that the early courses teachers take would have a relatively larger impact, but more advanced courses would add little or no further benefit. This may explain the wide variability in apparent benefits of majoring in either mathematics or education. Majoring in either subject appears to have negative effects on elementary teachers’ effectiveness and also on secondary teachers’ effectiveness, though the secondary estimates are far more variable.
There is also evidence that teachers with different personal qualities may have differential effectiveness. For example, students learn more from teachers who graduate from more selective institutions. We base this conclusion mainly on TFA studies, since the two regression studies of institutional status yielded inconsistent findings. The effects of TFA’s selective recruitment are somewhat larger than those of individual courses teachers take across all colleges, but they do appear to be consistently positive.

Finally, there appears to be a negative effect associated with obtaining an advanced degree in education, and a positive effect associated with obtaining an advanced degree in mathematics. We suspect that this pattern may also reflect differences in the personal qualities of teachers who seek out these degrees, which are not required for an initial teaching certificate, but for which there are often financial incentives to pursue.

Particularly surprising here is the difference between the observed patterns of effects and the conventional wisdom about teacher knowledge. Among the four hypotheses that motivated this analysis, the most contentious is pedagogical knowledge. Teacher educators believe they have meritorious and important content that teachers need to know, but skeptics fear that these courses are rarely beneficial and that teachers would be better educated if the space currently reserved for education courses were released. The least contentious hypothesis is that content knowledge is essential: virtually all advocates support the importance of content knowledge. Yet the differences we see in these data do not suggest such a differential conclusion. Data in Figure 61.1 suggests that mathematics education is more beneficial than mathematics per se, and data in Figure 61.2 suggests virtual comparability across the content domains, with mixed results in all three domains and at both elementary and secondary level. Data in Figure 61.3 shows a modest benefits to courses in all content domains, while data in Figure 61.4 shows marked variability in estimates of the benefits of majoring in either education or in mathematics. It is not until we get to the level of advanced degree that we see a clear difference between education and mathematics, and these differences are based on a single data base.

Taken as a whole, our evidence does not suggest that education courses are harmful except at the graduate level. Indeed our evidence suggests that, in moderation, education courses are beneficial. At the same time, our evidence also does not suggest that mathematics courses are entirely beneficial. Instead, it suggests that that there may also be a limit to the number of courses in mathematics that will benefit teachers. Perhaps a good next step for researchers would be to consider non-linear models when testing these hypotheses, and to examine their models more closely for aberrations that might be influencing outcomes.

We suggested at the outset that, although most advocates for coursework in education are also in favor of courses in other domains, and are in favor of bright, well-educated teachers, whereas advocates for these other hypotheses tend to be quite skeptical of education coursework. In an adversarial setting, it will be tempting to dismiss equivocal findings about one domain while embracing equivocal findings about another. A better response to the data would be to begin a program of research that more closely examines the content actually taught in various courses and to generate more nuanced hypotheses about what it takes to learn to teach. Both mathematics and teacher education departments could benefit from a closer examination of the content they offer to prospective teachers, with an eye toward its relevance. Mathematics departments might want to examine the relevance of advanced mathematics coursework for teaching. Teacher education departments certainly need to examine the content they provide in their advanced degree courses.
NOTES

1 Work for this paper was supported by a grant from the U.S. Department of Education, Institute for Educational Sciences, and by the National Science Foundation, Program on Research, Evaluation and Communication. Responsibility for the content and quality of the paper reside solely with the authors.

2 Though we use the term “value added” in our title, we use it in a more general sense than it is sometimes used. In the literature, this phrase sometimes refers to a very specific analytic approach (Kupermintz, 2002; Sanders & Horn, 1994) and sometimes to the general approach of using pretests to control for prior achievement in a statistical model (Cunningham & Stone, 2005). We use it here in the more general sense.

3 We eventually expanded our list of qualifications to include some things that typically are acquired after teachers obtain full-time teaching positions because these things may be relevant in district hiring or salary decisions. These include, for instance, teachers’ years of experience, whether or not they possess an advanced degree, whether they had been certificed by the National Board of Professional Teaching Standards, and how they responded to a commercial hiring interview such as the Teacher Perceiver Interview. These later additions have no bearing on the present study.

4 There were a few cases in which authors did not provide this information. When they did not, we sometimes found relevant information in another research report that used the same data base and sometimes from a web site that presented population statistics. The general goal was to find a population average pre- and post-test score that could be used as a benchmark for examining the size of teachers’ effects on students.

5 Since these authors did not provide information on average students’ change during the year, we present their findings using raw scores. We are unable to say whether or not these differences are substantial relative to average gains.

6 Another recent study, by Laczko-Kerr (2002a, 2002b; Laczko and Berliner, 2001; Laczko-Kerr and Berliner, 2002) was rejected because it did not employ a pretest.

7 The Darling-Hammond et al. study actually includes effects as measured by several different tests, and the authors argue that, in the Houston situation, the other tests may be better indicators of student learning. However, we prefer the TAAS test because it is the assessment that is aligned with the state curriculum and that teachers are accountable for. Since, in all cases, we take only one model per study sample, to avoid data dependency among effects, this is the only estimate we take from that study.

Artifacts
9.1 Purposes of a normal school

William S. Learned,
William C. Bagley and others

In 1914, Governor Elliott W. Major of Missouri obtained the support of the Carnegie Foundation for a study of the teacher education problems of his state. In organizing the study, William S. Learned, of the Foundation’s staff, enlisted the services of people who were, or were destined to become, shapers of “professional” thought about American education. Among them were: William C. Bagley of Teachers College, Columbia University, whose students established the field of teacher education as an area of specialized scholarship; Charles A. McMurry of Illinois Normal University, George Peabody College for Teachers, and Teachers College, an expert on “methods of instruction” who had led the early Herbartian movement in America; Ned Dearborn of Harvard University, one of the early advocates of scientific measurement in education; and George D. Strayer of Teachers College, who perhaps as much as any one man made the school survey a permanent feature of American life.

Missouri was their laboratory, the nation their audience. Their survey was the first of several massive studies of American teacher education. Paradoxically, though their techniques represented the wave of the future, their basic values and assumptions were quickly to wane. In no subsequent major study will be found so complete a consensus in favor of the single-purpose teachers college.

1 THE EXISTING CONCEPTION

“What should a normal school be?” This is a question which, according to Joseph Baldwin, the first president at Kirksville, “only the angels can answer.” Whatever the accuracy of this verdict, it is possible at least to discover what the function of the institution has been as worked out in practice in Missouri.

Early conception of the function of a normal school

The question may be reduced to the following alternatives: the normal school shall either provide a general education, making its professional features more or less incidental, or it shall undertake to give an intensive professional training, exclusively for teachers. Of these alternatives, Missouri at any time in her early normal school history would have emphatically asserted the latter. From the beginning, the movement was in the hands of men who had unlimited faith in the professional idea. Its appeal was founded on the prevailing low state of training among common school teachers, and it was promoted by teachers, superintendents, and associations of these, who had definitely in mind the elevation of the class as a whole. So in 1871 the State Teachers Association at Chillicothe resolved “that the normal schools should be at the head of our educational system;
that the course should be purely professional; and that all preparatory work should be done in the
public schools and universities.\textsuperscript{1} The early curricula exhibit this predominant idea very clearly: it
was never a question of giving or of not giving the professional subjects, but always of how much
academic material would suffice to supplement the defective preparation with which most stu-
dents came equipped. All subjects were presented or reviewed from the standpoint of their
most effective presentation to a class, and the practical usages of instruction received heavy
emphasis. "No effort has been spared to make the institution exclusively a school for teachers."
\textsuperscript{2} "In arranging the course of instruction strict regard has been paid to the requirements of the
public schools of Missouri, and in carrying out that course our constant aim has been to give such
training as will best qualify the graduate both intellectually and morally for effective work as a
teacher."\textsuperscript{3} These statements from Warrensburg in 1878 and 1886 reveal the attitude of the other
schools as well. President Baldwin, at Kirksville, declared in 1872 that "every energy is directed to
preparing for the public schools of Missouri the largest number of good teachers in the shortest
time," and in 1880: the aim of the school is "to give culture and learning, not for the benefit of the
student, but that it may be used in the education of the masses."\textsuperscript{4} Especially instructive are the
observations of State Superintendent Monteith, who was in office when the schools were started:

It is a pretty well-defined result of experience, too, that normal schools should be quite
elementary in respect to the subject matter and curriculum of study. In a school system
which embraces high schools and universities, there is not the slightest reason why the
normal school should duplicate the instruction of these more advanced institutions. I am
thoroughly convinced, in observing the mistakes of other states, that the normal school is
disappointing the object of its design when it drifts away from the common schools of the
country. With this object steadily in view, our Board of Regents are endeavoring to adjust the
two schools already established to the special conditions and wants of the state. The higher
mathematics and dead languages, except within a certain eminently practical limit, are to
give way to a more generous attention to natural science, drawing, and the perfecting of
teachers in the best methods of conducting the common branches of the common school.\textsuperscript{5}

Missouri normal schools, therefore, were founded to train teachers. To say "exclusively" would
be technically wrong, as certain readjustments were occasionally made here and there; for
example, special classes in Greek were sometimes offered to accommodate a few who wished to
go to the university, and certain individuals were occasionally present who did not declare their
intention to teach. But the clear and consistent aim apparent under all circumstances was to
provide teachers, actual or prospective, with special skill for their duties, and in their reports to the
legislature all the schools were solicitous to show that the largest possible proportion of their
students were actually teaching in the state.

Subsequent variations

This fixed purpose of the first thirty years has wavered in some schools during the subsequent
period. The three original institutions furnish an interesting contrast in this respect. In 1909, under
the caption "People’s College," Kirksville announced itself as follows:

The State Normal School, Kirksville, Mo., is attempting to do a great work for the people of
the state by giving studies reaching from the kindergarten through the most advanced col-
lege courses. This wide range of work—meeting the demands of all the people—is found in
very few first class schools. While advanced common school courses are given in this
institution for the benefit of those who are preparing to teach in the rural and ungraded
schools, academic degrees are conferred upon those who have completed the work offered
This brings the school in close touch with the people by giving an elaborate education to those who want to enter the professions, and a vocational education for those who want to take practical business courses. It cannot be denied that the Normal School comes nearer the people than other schools and may therefore be justly called the People’s College.7

This statement is followed by an extensive program of courses that are clearly not intended for teachers—one year curricula chiefly in farming and commerce. Nowhere in this bulletin, furthermore, is there a clear statement that the school is of a limited professional character, or that a declaration of intention to teach is required. It holds out rather an alluring vision of a sort of educational lunch counter where everything “the people” wish, may be had in portions suited to their convenience.

The “People’s College” idea does not appear to have thrived; at any rate, nothing more is heard of it, and the catalogue of the following year goes back plainly to the original aim: “The Normal School is not a college for general culture. It is a vocational institution of college rank. Under the law its students declare their intention to teach in the public schools.” The subsequent catalogues have shown a single, strong professional purpose.

At Cape Girardeau an enlargement of scope was announced in the same year as at Kirksville. The catalogue of 1909 declares: “The Normal School has a larger mission in Southeast Missouri than that of a state college for teachers . . . The institution must be to this section of the state their one great college. It is fully equipped to meet the demands that are naturally made upon it. In its college courses; in its agricultural courses; in its Manual Training School; in its domestic science and domestic art courses; in its School of Music; in its business courses; and in its teachers’ college the people of Southeast Missouri will find the opportunity to educate themselves for their life work.” Tho placing its teachers college last in the above list, the school elsewhere in the catalogue clearly defines its legal teacher-training function as a portion of its activity. In the catalogue of 1910 its “Field of Service” is formally described as comprising “A School for Teachers,” a “Subcollegiate” department, and “A State College,” the latter offering (since 1907) courses leading to the degree of A.B. and requiring in them no work in education whatever. Here we have, therefore, an institution deliberately revising its organization throughout and introducing, not one-year vocational courses as at Kirksville, but an elaborate curriculum with a new and alien purpose. It is difficult to see how either school could reconcile these departures with the law’s demand for an exaction from each student of a declaration of intention to teach in the schools of Missouri. Cape Girardeau, and possibly Kirksville, has been saved from embarrassment thru the fact that but for a single case no graduate has taken the courses except prospective teachers who could also avow their intention to teach; that, however, scarcely justifies the appeal for students distinctly excluded by law. This divided purpose at Cape Girardeau has never been abandoned. On the contrary, it has been officially reaffirmed in the school’s magazine publications of 1913 and 1914,8 where the pledge to teach is declared to be out of date, and it is frankly proposed to adapt the institution to the needs of men and women who will teach but a short time, if at all, and whose professional interest is therefore incidental at best.

Warrensburg, on the other hand, has consistently adhered to the original plan, to the extent, at least, of an unequivocal announcement of her special aim in every catalogue down to the present year. An expression in the school’s biennial report of 1885 is a fair sample of the early attitude: “On all proper occasions we have taken pains to spread abroad the impression that this school is designed for the training of teachers and for no other purpose whatever.” In the catalogue of 1904 the “Object of the School” is defined in the following paragraphs:

In the law creating Normal Schools in this State the following passages occur: “The course of instruction shall be confined to such branches of science only as are
usually taught in Normal Schools and which may be necessary to qualify the students as competent teachers in the public schools of this State.

“Every applicant for admission shall undergo an examination in such manner as may be prescribed by the Board [of Regents], and they shall require the applicant to sign and file with the Secretary of the Board a declaration of intention to follow the business of teaching in the public schools of this State.”

The following is the pledge required of every student upon entrance and registration:

“I hereby declare that it is my intention to follow the business of teaching in the public schools of this State, and that I voluntarily enroll myself as a student in the State Normal School at Warrensburg for the purpose of preparing for that work.”

The limits prescribed for the course of study and the form of the pledge show that but one purpose was contemplated by the State in establishing these schools, viz.: The training of teachers for the public schools of the State.9

Similarly in 1905 and after, the school’s “sole function is the preparation of teachers for the schools of Missouri,” “The school does not exist for the benefit of its students, but for the benefit of the whole people.”10 And in 1912: The school’s “sole purpose is to confer on its students that education, discipline, professional training, and practical skill which will best fit them for teaching in the public schools of the State.”11

The schools at Springfield and Maryville, founded in 1906, have in general followed the exclusively professional ideal also, as their catalogues attest. Southwest Missouri has been an unusually fruitful field for such single-minded service, and the school at Springfield has prospered remarkably. Maryville, in 1914, devotes two pages of its catalogue to the exposition of this distinctly professional aim. It is with some surprise, therefore, that one sees it weakened in 1916. The school now calls itself simply “an educational institution,” and, besides enumerating the various teacher-groups that are provided for, invites also those who are “seeking to secure the preliminary college academic requirement” for the university, or students from other colleges who seek “to extend their credits in college,” and finally observes “that many persons not immediately concerned with teaching find pleasure and profit in becoming enrolled in our classes.” There is no reference to the declaration of intention to teach required by law.

Special considerations affecting a normal school’s conception of its function

Before discussing the merits of the question involved in these divergent proposals, there are certain additional facts to be considered. In spite of the professional ideal that, with the above exceptions, has dominated the schools, the notion of a general education has almost unconsciously, and for historical reasons, influenced their purpose. From the beginning the students in these normal schools have been exceedingly heterogeneous, with a preponderance of mature minds of good ability but with very defective preparation due to lack of opportunity. The all-important preliminary process was therefore necessarily one of fundamental education, and it is impressive to note how consistently the Missouri normal schools have urged this principle, even tho at times they appear to have failed to practise it. Throughout their history they seem to have been ardent advocates of having something to teach as compared with certain schools in other states that sacrificed their character on the altar of “method.”

Pressure for academic credit

Furthermore, it should be noted that as purveyors to that occupation of teaching whereby chiefly needy and ambitious boys and girls obtained the means for further education, these institutions
stood in tempting relation to the fuller education that their students sought. It was a matter of course that the kind of student who came to the normal school had taught or would teach: teaching was his most obvious resource for temporary support. Hence in very many cases the student accepted professional work as a necessary incident, while his real attention was upon the academic work that would be accepted for credit in another and higher institution. It was but a step, and a very natural step, for the normal school to develop its requirements with such an end in view. A genuine desire to prove serviceable to hard-working students who were using the teaching profession merely as a ladder, and a less worthy feeling that such students brought to the school not only numbers but prestige, combined to enhance the "college" idea as a legitimate goal. Aside from Cape Girardeau's wholly non-professional curriculum already mentioned, the sixty-hour curriculum for high school graduates at Maryville, in 1914, illustrates such a purpose: in the effort to offer only subjects that might be used for credit elsewhere, no special study of the history, geography, and arithmetic that these students were presumably later to teach was required, except as it appeared fragmentarily in ten semester hours of practice teaching.12

That pressure of this sort has been and still continues to be severe seems evident from the replies made by students to enquiries at the various schools. Sixty per cent of the students in attendance at the time of inspection declared that they did not intend to teach permanently. With the women the factor of prospective marriage probably weighs heavily; this cannot, however, be true of the men, seventy-eight per cent of whom make the negative reply. Such students naturally have little interest in an intensive professional training; those studies please them best which give them the most credit for future use. Even the men who are intending to continue in the field of education find but little inducement in the work properly expected from most of the women. The latter expect to teach, while the men hope to go directly into administrative positions. As a group the men in the normal schools seem to be a disintegrating element, yet the efforts made to attract and retain them indicate that their presence is nevertheless much preferred to a homogeneous professional group more largely made up of women.

**Effect of local control**

A third motive for stress on general education has arisen from the complete local attachment and control of the schools. The town or county has paid a heavy bonus for the location, and naturally exercises proprietorship. The schools are severally in the hands of local boards, who really own them in behalf of their respective districts. They are maintained largely, to be sure, out of state funds, but the amount of such appropriations depend upon the energy and influence of their board members and friends who lobby vigorously, and is never in any sense the considered proposal of a state authority directing the institution solely for the good of the whole state. They become, therefore, the local public educational institutions; and the fundamental theory of a school to train public servants for the benefit of the state is largely obscured by the more attractive idea of a place where, local youth may prepare for college, or even pursue collegiate studies and acquire degrees. Town or sectional pride urges this interpretation on the institution, which in turn is anxious to recruit its numbers because of its feeling of responsibility to the local community.13 Regents with pet notions find an easy field of influence, and often have slight perception of the larger purpose of the school. One of these urged that, as his school had an old telescope in its possession, it should undertake collegiate courses in astronomy. Administrators naturally yield most quickly to the forces that feed and affect the school, and when dependent solely upon such local influences can scarcely be blamed if truer ideals seem distant and impracticable. It is easy, under these circumstances, to include the professional idea, because, as already pointed out, it fits the economic situation of most of the student patrons; but to make it really the sole and sufficient reason for the school's existence is less easy, and probably cannot be fully accomplished under the present system of control.
"Democracy": the justification

The situation described in the foregoing paragraph has, of course, developed a theory, or the interpretation of a theory, for its justification. Great emphasis is placed on the perfectly valid creed that the people know what they want, and that democracy in education consists in gratifying their desires. But from this creed there is then drawn the inference that because the people desire good teachers, the people are therefore competent to direct the institution that provides them, and that the institution is most “democratic” that yields itself most completely to the popular local fancy. Such, unfortunately, are the terms on which it is often possible, thru spectacular features, to develop a large school; but such is not the way to give the people what they, at heart, desire. An intelligent society has learned not to interfere with competent professional service when it would be healed or seek justice at court; that service commands the maximum confidence which, for a selected end, most completely refines and dominates its choice of means. This temper is superlatively characteristic of a good school; it must mould and dominate public opinion in its field; it must guard its aims and processes from public interference precisely in order that the public may get the service that it wants. No other interpretation of public service is worthy of a democracy, but the present system of local control makes such detached and efficient service difficult if not impossible.

Professional training: long uncertain as to its method

Finally, the development of professional training itself has involved the conception of general education in an ambiguous and confusing manner. When the Missouri normal schools were established, two theories existed as to their operation. According to the first, the purpose of the schools should be solely to teach subject-matter properly; it was said that students would teach precisely as they had been taught, and could shift for themselves if filled with ideas to be communicated. According to the second theory, only the indispensable subject-matter should be given; the main purpose should be to develop the philosophy of method and to test the skill of the candidate in using methods. The latter theory was the one adopted and chiefly followed, although, as has been said, the schools appear to have insisted usually that the foundation of subject-matter should be substantial. Little by little, however, both in Missouri and elsewhere, the whole normal school practice seems to have hardened into a formalized method from which the schools were aroused thru criticism by the universities. The latter had been persistent adherents of the first of the two doctrines noted; consequently the cult of “method” received little but ridicule, and in so far as it had developed a pose to hide its insufficient learning, its pretensions were quickly punctured. Under the fire of this attack many unworthy accretions of “professional” lore disappeared—sentimentalism, mystic reverence for formulae, a not infrequent quackery; while such conceptions as survived the refining process were eventually accepted for use in normal school and university alike.

Apart from this salutary process, however, and somewhat preceding it, came an increased mechanical emphasis on what the university primarily stood for, namely, content. In Missouri this is illustrated by the change that came over all the institutions about 1900, when within two years the headship in each was transferred to a new man. The university high school inspector and former state superintendent of public schools went to Kirksville with a commission from the president of the university to “go and put scholarship into that school.” The president of Central College at Fayette, Missouri, went to Warrensburg, and a successful school superintendent, a graduate of the state university, went to Cape Girardeau. The effect of this infusion of fresh academic blood became immediately apparent in the announcements of the schools: the cultural idea; the proposal, in order to make teachers, to make “first educated men and women;” the notion of “a broad academic foundation” are all insistently emphasized. Accordingly, the studies
considered “academic” were set off sharply from those termed “professional,” and commanded a certain special respect if only because they were terms shared in common with the higher academic world; and this distinction has in general been pronounced even to the present day.

The influence of this development has been marked both on the students and on the institutions. In effect the school has unconsciously said to the student: “This academic foundation is your education; it is of prime importance, it has nothing to do with teaching, it is what you want for life, it will serve you if you proceed to college or professional school; as a teacher-preparing agency we are obliged to hang in your belt certain tools that will get you a license and may be useful if you teach, but they are not big enough to be in the way if you do not, and an educated person ought to have them anyhow.” Thus its very endeavors to meet more satisfactorily its professional purpose by strengthening the academic foundation have created in the normal school a divided aim which it has not known how to unify, and of which the various other centrifugal tendencies already enumerated have taken full advantage.

In its effect upon the institution itself this situation has been positively disastrous. With the emphatic division of subjects into academic and professional groups came naturally a corresponding division of the staff. Teachers of educational subjects, including the practice-school director and supervisors, should be the core of the institution; distinct from them are the academic instructors, who generally will have nothing to do with the practice school or its works. In members of the academic staff, pride of subject, and often of better training, has bred not a little scorn (carried over, perhaps, from the universities from whence they came) for the department of “pedagogy” and the ill-paid supervisors of the training school. At any rate, these academic instructors have rarely been selected for their knowledge of how to teach young children; their interests and sympathies are elsewhere, and the organization of the school has usually failed to exact from them responsibility for this phase of their duty.

In some normal schools, not in Missouri, the faculty is split from top to bottom on this line, and even in Missouri, with the sole exception of Springfield, the cleavage is apparent. The inevitable tendency of such division of sympathy and purpose is to reproduce itself in the mind of the student. His strictly educational courses lack conviction because they lack relation, and fail of the illustrative and cumulative force latent in the so-called “content” subjects; the latter, in turn, conceived as ends in themselves for “general education,” terminate often in a series of blind alleys whence the student neither gets further nor sees how his achievement affects his main purpose.

2 NORMAL SCHOOLS SHOULD TRAIN TEACHERS

It is the judgment of the authors of this report that institutions established by the state to prepare teachers as public servants for its schools should make that business their sole purpose and concern. The character of such preparation is a question of administrative knowledge and policy. It will depend upon the amount of financial support available, and will be modified by the varying need for teachers in the state and by the rewards offered in the communities to be served. But with their method and specific goal thus defined, no consideration whatever should divert such schools from their task.

The grounds for this conclusion are simple and obvious. The question is one of institutional economy. Each school has a certain amount of energy expressed in terms of its annual appropriation plus its organization and permanent plant. With this energy it confronts a definite and difficult task contemplated in the statute, namely, with the help of four similar schools and of the university, to place a competent teacher in every teaching position in the state. This is a task with which these six schools have scarcely begun to cope. It is a task so great that large and important portions of it have temporarily to be farmed out, as in the inevitable allotment for the present of
the teachers of the large cities to the city training schools, and of rural teachers to the high school
training classes. Hitherto the schools have trained a few teachers thoroughly, and have given a
meager smattering to a vast number. Even the few have received a generalized training which will
not be tolerable longer if the reasonable demands of educated communities are to be met in
Missouri as they are already met in some other states. There is an overwhelming need for more
prolonged and more intensive training, extended to include as many as can be reached. In the
face of this heavy obligation which the state lays upon the normal schools, it is difficult to justify
the proposal of any school, say of Cape Girardeau, to use its share of the all too scanty training
funds to develop a local university. This means, as indicated in the prospectus already quoted, to
relegate its training of teachers to an inconspicuous department; to promote the other phases of
collegiate work for their own sake and not alone as they produce better teachers; to fill classes, as
college classes are now filled, with some who will teach, some who will farm, some who will be
politicians, and many who have no specific purpose; in other words, to sacrifice the enormous
advantage of momentum and morale that inheres in a single fine idea well worked out, for a round
of inevitable mediocrity. For the school has at best wholly insufficient funds for its present logical
purpose—the preparation of a competent teacher for every position in its district. To take over
other projects, as these are conceived in modern education, is not only to fail in its proper task but
to fail altogether.

The case of Cape Girardeau is especially interesting, inasmuch as for many years both regents
and administration have made every effort to realize this “larger” nation. Elaborate advanced
“college” curricula, special scholarships “for graduates from other colleges,” and an enthusiastic
literature have all pushed the idea. But only a single graduate has as yet (1917) gone out from
such courses; the school is still as solely a normal school as is any of the other four. And with good
reason: Cape Girardeau has taken pride in being a good school, and both teachers and students
have dimly perceived that it was impossible to be a good normal school and a “great college” on
the same appropriation. There is doubtless truth in the claim that, as college attendance is in great
part local, more southeast Missourians would go to college if they had one nearby. But it is just
as true that a good normal school is a professional school throughout and cannot be an arts
college; if it wishes to conduct a college that is self-respecting, it must have double funds,
separate classes, another faculty selected for that purpose, and so on. The combination is not a
happy one in any place where it is now on trial, and the logic both of theory and experience is
against it. The college agitation at Cape Girardeau has probably done good rather than harm;
some public interest has been aroused, and a college foundation may some time seize the
imagination of the wealthy men of that region or be developed from the local high school by way
of a junior college as elsewhere in Missouri; but the obvious way to help in bringing about this
result is for the present institution to discharge its own peculiar task well, and to fix its ambitions
on becoming the best purely professional training school for teachers in the Middle West.

Cape Girardeau is an excellent illustration of a school-appropriated body and soul by the local
community in the hope of making it the engine of local ambitions. The town and county bought
the school in the first place, and can scarcely be blamed for owning it now. Fortunately state control of
the funds, by forcing it into comparison with the other schools, still determines ill general line of
action, but it can probably never reach its maximum power until it acquires a controlling board
disentangled from local concerns and sympathetic with its proper purpose. Reimbursement of
this and the other counties for their original outlay would be a small price to pay as compared with
the benefit of independent management.

Obstacles to professional training are disappearing

Other obstacles to an exclusive and intensive professional development in normal schools are
happily vanishing. Secondary work, to which the normal schools have hitherto of necessity been
tied, seems destined early to disappear from them. The phenomenal increase in high school facilities has brought secondary education within the possible reach of nearly every student, and the higher institution owes it to the lower to turn back every pupil of high school age who can attend a local or neighboring school before coming to the normal school. Many of these country high schools have large contingents who come in for the week from the surrounding territory. Especially where training classes are installed, every consideration appears to favor the development of local training centres for secondary work. Mature persons, for whom the high school makes unsatisfactory provision, should be given opportunities elsewhere.

The question of relation with other higher institutions is likewise being disposed of successfully. As this problem has existed, however, an important distinction should be made clear. It is one thing for those who have taken a strictly professional course and who expect to give themselves seriously to teaching to urge that they be allowed to continue their preparation in other institutions without loss of credit; it is quite another thing for persons who have no such intention to demand that the normal school give them a general education that will see them into college and professional school. For the first group adjustment has already been accomplished. Two-year graduates of the normal school may enter the School of Education at the university without serious loss of credit, and the recent conference arrangement between normal schools and university provides that students doing four years of standard work at a normal school may be admitted to graduate work in education at the university. The second group should be dealt with drastically, as the institution values its professional integrity. If elementary and high school instruction in this country is ever to be cleared of its traditionally random and trivial reputation, training agencies must insist on a curriculum so specific in character as to make its choice a fateful step in an individual’s career. There will doubtless always be quondam teachers who fail and practise law, just as there are quondam physicians who fail and sell insurance, but it is intolerable for an honest training school so to relax its administration and enfeeble its courses as to put the transient at ease. Every normal school student should feel behind him a full tide of pressure from every quarter urging him to teach and to do nothing else, and he should contribute the impetus of his own clear decision to the general impulse.

**Unity of aim increasing**

Finally, in the professional training itself there are discernible strong tendencies making for unity. The present schism in staff and curriculum was the result, at first, of the difficulty of securing competent teachers of academic subjects who possessed likewise a thorough training in education and successful experience in teaching children and youth. This is still an unusual combination, but, thanks to rapid growth of schools of education and to improved product in the normal schools, it is becoming less rare. In the case of the curriculum, the result seems to have been due partly to unsympathetic instructors, but more largely to a desire on all sides to swing as far as possible toward the collegiate idea and away from the earlier attitude. It is now evident that this emphasis has been greatly overdone. The normal school that is true to itself finds it impossible to be a college. A genuine professional purpose makes itself felt much further than the purely technical subjects; it governs the selection of material for every curriculum, it grips every course that is offered, and that in no perfunctory fashion as formerly, but with a clear, scientific conception of the ultimate aim in view. “With a mission like this, why waste time trying to be a college?” is the convincing retort of the modern training school. Again, if this clearer definition of aim affects the attendance of men at the schools, let the situation be faced frankly. There is nothing to be gained for the profession of teaching by catering to a set of individuals who definitely intend to make their normal school course and a year’s teaching a step to other work. Such a procedure cheapens the course for its proper candidates, and advertises most effectually that teaching is a makeshift occupation and preparation therefore a farce. It is certainly most desirable to make the
teaching profession attractive to men; but, given higher financial rewards, the surest way to convince them that there is something to it is to make it genuinely selective in respect to length and character of preparation. If they cannot be held on these terms, there is no help for it; any other condition is illusory and dishonest.

A normal school’s obligation to the state

The efficient teacher-training school of any grade is not to be measured by college, university, law, medical, or other liberal or professional institutions. These operate indirectly for the general good, but their direct aim is rather the intellectual or vocational benefit of the individual. The school for teachers, on the other hand, is the immediate instrument of the state for providing a given number and quality of public servants to discharge the main collective obligation of society to the next generation. Salaried staffs of physicians or lawyers supported by state or city for the whole people would imply a similar function in medical and law schools. Even so, the large number of teachers required, in proportion to the number of doctors and lawyers, would tend to elaborate and standardize the teacher-training agencies above other schools. Private and outside sources would not play so large a part, nor would such wide individual variation be acceptable in preparing five thousand as in furnishing three hundred.

In view of this peculiar relation to the state it is evident that, to be effective, the training institution should have two characteristics in a preeminent degree. First, it should have a vivid purpose. Its sole aim being to train teachers, every item of its organization should contribute either to the final excellence of its product, or to the creation and maintenance of conditions in its region that will make its product most successful. Irrelevant work that can be done elsewhere should be discontinued as soon as possible; bogus or uncertain candidates should be rejected; diversions of aim, however attractive, should be avoided. The school should do one thing and do it mightily. In the second place, it should be wholly responsive. First and last it serves the state and not individuals; as an efficient instrument it must be sensitive to control. New types or altered numbers of teachers, fresh courses to be added, higher standards to be set,—all of these should find the training school prepared for continual and automatic readjustment. The informed and authorized directors of the state’s educational policy—and the state should obviously have such directors—should not find themselves helpless because of institutional conservatism, opposition of alumni, or local entanglements. To ensure this, the school clearly should not be entrusted to an irresponsible head for personal exploitation; the measure of excellence in administration should be a quiet and rapid accommodation to the changing demands of the state’s educational authority. The loyalty of alumni should be won, not for persons or places, but for the skill with which the school does its work and for its flexible adaptation to its duties; the head of an institution who, by personal appeal to numerous or powerful graduates, seeks to swing his own policy at all costs is abusing his trust. Finally, to be responsive, the school must be free from local pressure and interference. The state as a whole invariably wants for itself better things, and defines those wants more wisely than can be the case in any but highly developed urban districts. To tie a school down to the limited vision of a small area is to deprive the community of that margin of superiority which the whole state has achieved and formulated.

NOTES

2 Ibid., 1878, page 224.
3 Ibid., 1886, page 108.
4 Ibid., 1872, page 166.
12 Good normal schools elsewhere were at the same time requiring 12–15 semester hours in these subjects aside from a full semester of practice work.

13 An everywhere vigorous and vocal expression of this town pride rises from the vested interests dependent on the schools—boardinghouses, stores, churches, and so on. Thus, a writer in the local newspaper of one of the normal school towns struck a responsive chord when he declared that the present study would undoubtedly discourage the attendance of men at the school, and send both men and women to “enrich the boarding houses of some other place.” *Kirksville Express*, December 10, 1914.

14 These two points of view are well stated in one of Superintendent Monteith’s discussions. See *State Report*, 1872, page 37.

15 The Revised Statutes of 1909 declare that “the course of instruction in each normal school shall be confined to such subjects in the sciences and arts as are usually taught in normal schools and necessary to qualify the students to become competent teachers in the public schools.” See Chap. 106, Art. 14, Sect. 11071. An Act of 1919 extends this to include “such subjects in the arts and sciences as are usually taught in teachers’ colleges, normal schools or school of education,” Sect. 11075.

17 See ibid., page 300.
9.2 A quarrel among educators

James Bryant Conant

Universities have existed for nearly a thousand years. Their periods of vitality have been marked by passionate debates among professors. A clash of opinion has often been the prelude to a fruitful development of new ideas. Bitter theological disputes in the Middle Ages, as well as the violent controversy over Darwin’s theory a century ago, might be cited as examples of quarrels among educators. But the quarrel I have in mind in writing this volume is of an entirely different kind. Neither factual evidence nor theoretical speculations provide the battleground. Rather, this quarrel might be described as a power struggle among professors, which has come to involve parents, alumni, legislators, and trustees. Let me illustrate the nature of the battle by recording my own involvement during the course of nearly fifty years.

Early in my career as a professor of chemistry, I became aware of the hostility of the members of my profession to schools or faculties of education. I shared the views of the majority of my colleagues on the faculty of arts and sciences that there was no excuse for the existence of people who sought to teach others how to teach. I felt confident that I was an excellent teacher and I had developed my skill by experience, without benefit of professors of education. I saw no reason why others could not do likewise, including those who graduated from college with honors in chemistry and who wished to teach in high school. As joint author, with my former chemistry teacher, of a high school chemistry textbook, I was quite certain I knew all about the way the subject should be presented; I doubted that my understanding was shared by any professors of education. When any issues involving benefits to the graduate school of education came before the faculty of arts and sciences, I automatically voted with those who looked with contempt on the school of education.

Suddenly, after being a member of one faculty for fifteen years, I found myself in a new position. I became the presiding officer of all the faculties of Harvard University. I was responsible to the governing boards for the budgets and the welfare of all our undertakings, including that of training teachers. It soon became evident that the antithesis between the views of the professors who taught the usual college subjects and those who were instructing future teachers was not as simple as I had thought. In the circumstances, it seemed reasonable to attempt to increase mutual understanding between the two hostile groups by establishing some arrangement through which they might exchange views and, if possible, learn to cooperate in their endeavors. The idea was obvious enough, though in the mid-1930s it was so unorthodox that a leading scholar in another university wrote the dean of the Harvard School of Education that “a shotgun would be needed to carry the wedding off.”

As a matter of fact it did not prove too difficult for a new president to persuade the two faculties to agree to the establishment of a joint board to administer a new joint degree, the master of arts in teaching. One faculty, that of arts and science, was to certify through its usual departments that
the candidate was well prepared in the subject to be taught in school—English, for example. The other faculty, that of education, was to certify that the candidate had successfully completed the courses in education that the administrative board had agreed were necessary. Since the School of Education, like the other professional schools at Harvard, was a graduate school, the question of offering courses in education to undergraduates did not arise. The candidates for the joint degree, it was assumed, would already have received a bachelor’s degree.

The scheme was accepted by the two faculties, but I can hardly say it was accepted with enthusiasm. Before more than a few years had passed, some of the members of the joint administrative board asked for a new committee to review the whole arrangement. The committee, composed of a few professors of education and a few from the faculty of arts and sciences, raised a fundamental issue. Had it not been a mistake to force a Harvard undergraduate to postpone his work with professors of education until after he had received the A.B. degree? Obviously he had started his preparation as a future teacher early in his college course by studying the subject matter to be taught. Why not arrange for a continuous five-year program with professors from both faculties involved in the undergraduate as well as the graduate work? Such a modification of the joint venture did not appeal to me as president of the University. I knew far too well the degree of hostility felt toward professors of education by the majority of the faculty of arts and sciences. It would be fatal to the whole idea to present a scheme based on the premise that a candidate for the bachelor’s degree could include in his program courses in education. Furthermore, the University had decided years before that professional preparation should be wholly at the graduate level. The School of Business Administration, for example, established a generation earlier, had rigidly adhered to this decision, and functioned only as a graduate school.

The entry of the United States into World War II so disorganized American colleges and universities that all concerned at Harvard lost interest in a second reformation of the education of teachers. After the war was over, the original concept of the degree of master of arts in teaching was accepted without question. And under the leadership of Dean Keppel the new system began to prosper. As the years went by, the hostility between the two Harvard faculties gradually diminished. I feel sure that a similar change was taking place in other institutions, yet from what my collaborators and I observed in the 77 institutions we visited in 1961–63, I am equally sure that the quarrel between educators is not yet over. As one dean of education remarked to me, “The boys have at least agreed to check their hatchets with their hats at the Faculty Club coatroom when they lunch together.”

While I am not prepared to say that there was, or is, actual hostility between educational and academic professors on every campus, there has always been a considerable gap between the two groups in a majority of institutions. Such a gap often exists in spite of fine word spoken by administrators about “an all-university approach” to the education of teachers, and the existence of a committee that symbolized the approach.

As long ago as 1944, I took the occasion of an invitation to speak on the 50th Anniversary of Columbia’s Teachers College to call for a “Truce Among Educators.” By that time, I had been thoroughly exposed to the views of the two camps, including their views about each other. After pointing out that, as is always the case in academic matters, errors had been committed by both sides, I suggested the terms for a cease-fire order. In brief, they were that the professors of education admit their failure to be sufficiently concerned with the type of youth who should go to college, and that the professors of the college subjects such as English or chemistry admit their ignorance of the nature of the high school problems of the 1940s, which were quite different from those of the 1900s. Indeed, the warfare had started primarily because of the revolution in secondary education. I reminded the audience that the expansion of the high schools of the country since the 1880s has been nothing short of astronomical. Instead of being concerned with the education of a very small proportion of the boys and girls from fourteen to eighteen years of age, the high schools now must accommodate nearly three-fourths of the entire age group. The mere
physical expansion, the mere change in scale, would in itself have presented a major problem to
the institutions of higher education concerned with the training of teachers, but another and still
more important factor entered in.

At the turn of the century, the high schools and their equivalents—the private academies and
preparatory schools—were essentially concerned with a group of young people who were studying
languages and mathematics, science and history. The enrollment in these schools in the
nineties usually represented either impecunious youths with high scholastic aptitude and a keen
desire for book learning, or children of well-to-do families who for social reasons were bent on
having their offspring acquire a college education. The combination of social motivation on the
one hand and high scholastic aptitude on the other presented the teachers of that day with a
relatively simple problem. What we now call an old-fashioned curriculum enabled the graduates
of those schools of the last century to enter college well prepared for further work in languages, in
mathematics, and in the sciences. Those who could take it found the formal instruction excellent;
those who couldn’t or wouldn’t dropped by the wayside as a matter of course. From the point of
view of those on the receiving end—professors in the colleges—this was a highly satisfactory
situation. What sort of education the rest of the fourteen-to-eighteen-year-olds received was
none of their affair!

In reviewing this bit of history in 1944, I was, of course, only reminding my audience of what
most of them already knew. Professors of education had been pointing out for several decades
that the faculties of arts and sciences had shown little interest in school problems. In the nine-
teenth century they had been quite ready to leave to the normal schools the task of preparing
teachers for the elementary grades. When social changes in this century transformed the nature of
the high school, the typical college professor himself was viewing with disgust and dismay what
was happening in the schools. (I am reporting on personal observation of fifty years.) With few
exceptions, college professors turned their backs on the problem of mass secondary education
and eyed with envy Great Britain and the Continent, where such problems did not exist.

My plea for a truce, made while World War II was still in progress, had little if any effect. In fact
the quarrel intensified in the 1950s because laymen entered the fray in increasing numbers and
with increasing vehemence. Schools have always been subject to criticism by parents, but after
the close of World War II, the criticism became more general and more bitter. The Russian
success with Sputnik triggered a veritable barrage of denunciation of those in charge of public
education. These attacks served to embitter the professors of education, who considered that the
work of their former students—classroom teachers, principals, and superintendents—was being
unfairly appraised. Since practically all public school administrators have studied at one time or
another in teacher-training institutions or a school or department of education, they are bound by
history and sympathy to the faculties of education. The same is true of a substantial proportion of
classroom teachers. Mutual loyalty between professors and former students has led to the forma-
tion of something approaching a guild of professors of education and their erstwhile students. An
attack on public education is therefore automatically an attack on schools and faculties of educa-
tion. As a matter of fact, the connection is not always so indirect. Many a violent critic of our public
schools has specifically attacked the professors of education.

One can understand the reaction of the members of the faculties of education, yet the criticism
to which they were being exposed was not without its justification. The deficiencies in our public
schools, particularly in our high schools, to which a number of writers (among whom I must
include myself) have called attention, were in no small part a consequence of their activities.
Despite the fact (often overlooked) that public school teachers and administrators have spent
many more hours in the classrooms of professors of arts and sciences than in classes taught by
professors of education, their attitude toward education has been largely shaped by the latter.
The writings of education professors have also influenced the outlook of many parents. The
emphasis on education for citizenship, on the socially unifying effects of the comprehensive high
school, and on the public schools as instruments of democracy, the recognition of individual differences, and of the need for including practical courses in high school elective programs—all these characteristics, which I applaud, were the fruits of the labors of professors of education. These men, most of them now no longer active, are entitled to a large measure of credit for making American schools what they are. But by the same token, the historian must charge against them some of those features of our schools that their younger successors and the general public have recently criticized so heavily. In particular, the failure to challenge the academically talented youth, to provide adequate courses in modern foreign languages, and to emphasize English composition—now widely recognized as faults of the 1930s and 1940s—are in process of being corrected.

What happened after Sputnik might be characterized as the entry of the layman in force into a battle of professors. What is now involved is more than a quarrel among educators. The academic professors1 have consciously or unconsciously enlisted the support of their alumni. We are therefore today dealing with two hostile camps. One camp is composed of professors of education allied with classroom teachers and public school administrators (though, like all alliances, it has its strains); the other is composed of professors of the sciences and the humanities and of influential collegiate alumni. Since the latter group includes radio and television commentators, editors, and publishers, the public school people and their mentors in some communities have faced a powerful set of forces. Along with the indignation of the professors of education frequently goes a sense of anxiety. "We who have shaped and improved our public schools are now being unfairly attacked, and there is danger that the public will be led astray!" Such thoughts are in the mind of more than one aging and honored individual who proudly carries the title of emeritus professor of education.

Why are the academic professors angry? What are they angry about? Many academic professors believe that the courses given by professors of education are worthless, and that the degrees granted students who have devoted much of their time to these courses are of little value. It is generally the case that the academic professors who advance these arguments know far too little about education courses. And unfortunately, what some professors of education have written about education can be labeled anti-intellectual. But what particularly irritates the academic professors is what professors of education say about teaching. After all, those who are engaged in college teaching usually pride themselves on their skill as teachers. And here are those who call themselves "professional educators" claiming that they and only they know what is good teaching! They imply, and sometimes openly state, that if all professors had taken their courses they would be better teachers! To make matters worse, in more than one state no one is permitted to teach in a junior college unless he has taken courses in education. If this is justified, the opponents ironically demand, why not require all teachers of freshmen and sophomores in four-year colleges to study under professors of education? To this question, professors of education often answer, "Such a requirement ought to be on the books."

And here we come to the issue about which emotions are most easily aroused—the issue of state requirements. Time was, not long ago, when in some states a school board could hire a teacher, and give him a permanent position, even if he had never even seen a professor of education. But those days are past. As a consequence, a graduate who has majored in an academic field must by hook or by crook meet the state requirements in education. (I shall be considering in a later chapter the various hooks and crooks now in use.) The fact that schools of education are beneficiaries of a high protective tariff wall is the single aspect of the present-day education of teachers that is most maddening to the academic professors.

In most states private schools can legally hire those they want. There is in these schools a free choice between teachers trained without benefit of courses in education and those trained as the state requires. Why shouldn't there be the same free choice in our public schools? The question is implicit in many of the attacks on schools of education. It is at the base of much of the hostility of
lay critics, many of whom can cite examples of high-standing college graduates who are forced by state requirements to devote a certain number of hours to courses given by professors of education. It is hard to overestimate the bitterness of those who attack schools of education with such cases in their minds.

An inquiry into the history of certification reveals that this issue has long been a breeding ground of controversy. The struggle to control entrance to the teaching office is an old one, destined perhaps to continue indefinitely. The motives for certification were clearly recognized when modern state systems of education first emerged from the medieval systems of church schools, town or guild schools, and universities. With respect to all these schools, first clerical and later secular authorities assumed responsibility to protect the young from teachers whose influence might be morally—in those days considered inseparable from religiously—destructive. As far as the lower schools were concerned, their function was viewed primarily as one of religious indoctrination. The public interest was deemed insured when competent authority attested to the religious orthodoxy and moral reliability of potential teachers. As far as the universities were concerned, a second factor—mastery of the material to be taught—was considered necessary. This mastery was attested to by the university faculty through examinations leading to a university degree.

But the university faculty was in origin a medieval guild—indeed universitas was a rather general term for an organized guild—and hence the granting of a degree took on the added meaning of controlling membership in a group granted exclusive vocational rights to conduct a particular social service. Thus the combination of licensure and degree-granting power served three purposes: first, it protected the students from immoral influence; second, it insured mastery of the material to be taught; and third, it defined a group to which exclusive vocational rights to the teaching office were given.

On the university level the guild was able, in some periods, to playoff secular and religious authorities against each other in such a way that the guild established exclusive control of certification for persons in higher education. On the lower levels the result varied from nation to nation and school to school. In some cases religious authority held, in others secular, and in still others a blending of the two.

In the United States local secular authorities early established control, with respect to publicly supported schools, of the total process of certification, though, of course, religious leaders sometimes acted as agents of the secular community. These authorities utilized two screening devices: character witnesses, and oral or written examinations. But since local boards were often hard pressed to find any teacher, they were sorely tempted to tailor the examinations to whatever candidate became available. Indeed in some rural areas the examiners themselves were too unschooled to develop and evaluate rigorous examinations even if they were inclined to do so. Finally, local ethnic or religious prejudices, personal favoritism on the part of some board members, and, it must be said, simple graft often entered the process.

As state systems of education developed in the middle decades of the nineteenth century, the emerging state Departments of Education began to take over the examination function. The rate of change varied from state to state, and in some cases the system of local examination persisted well into the present century. Though the legal sovereignty of the state in educational matters is clearly recognized, the state has never assumed total control of the actual certification processes from such major communities as New York City, Chicago, Philadelphia, and St. Louis.

In many states, public normal schools (later teachers colleges), controlled by the state Departments of Education, emerged simultaneously with the state system of public schools. Before 1850, state Departments of Education had begun to accept as a basis for certification completion of a course of instruction in one of the normal schools or colleges they controlled. This alternative to examinations simplified their tasks. Thus, by 1850 several states had two certification devices: first, completion of an approved course of studies in a state-regulated institution; and second, examinations.
When, at the turn of the century, American education expanded in terms of the number of students and schools, a further complicating factor entered the picture: the amount of knowledge available increased explosively; and the amount required for effective citizenship and employment rose rapidly as the social and economic system grew more complex and technologically oriented. The question raised in England by Thomas Arnold and Herbert Spencer about “what knowledge is of greatest worth” became acute in American education generally, and in teacher education explicitly.

Among the bodies of knowledge, or literature, that grew most rapidly, was that having to do with the process of education itself. The normal-school people developed an extensive literature concerning the “science and art of teaching,” and as university departments of education developed, research and speculation flourished both in them and in the related social science fields. Instructional materials ostensibly tailored to the growing interests and aptitudes of school-age youngsters came to abound. By 1900 the field of “education” had so developed that doctoral degrees were being awarded, and shortly thereafter one could specialize on the doctoral level in such fields as educational psychology, school administration, curriculum and instruction, and the history or philosophy of education.

In the normal schools, material concerning curriculum and instructional problems secured a major place. In universities in which a minority of the students and professors were directly concerned with teacher education, and in which the atmosphere was traditionally hostile to vocational education of any kind, the process moved more slowly. Since the state came more and more to depend for its supply of teachers on graduates of the universities and of colleges with traditional academic orientation, those who believed in the desirability of pedagogical courses found it necessary to utilize forces outside the colleges and universities. Their solution was a series of laws establishing requirements for courses in education to be taken by all candidates for certification. These early laws tended to assume that the collegiate and university faculties would make certain that the candidate was liberally educated and had adequately studied the subjects he proposed to teach. But college and university faculties were unwilling to tailor their academic requirements to the teaching assignments their graduates were to undertake, and as a result it often happened that teachers were not properly prepared in their subjects. When this became evident, the state certification officers began to require teaching “majors” of one sort or another. By this time, a new certification device had emerged: certification based on the successful completion of a specified set of courses taken in a collegiate institution which might or might not have been subject to state inspection and regulation.

It is important to note that such certification regulations were in a sense imposed on the universities and colleges as the result of pressure from a coalition of state Department officials and public school people. Just as the professors of the academic subjects had not, in general, been willing to assume active responsibility toward the public elementary and secondary schools, they did not welcome the responsibility for the professional preparation of teachers. Moreover, the academic faculties often felt that the professors of education employed to offer this instruction would not have been hired if it had not been for the state regulations, and resented what seemed to them external coercion. The professors of education, for their part, found that their own convictions coincided with those of state Department and public school personnel, and realized, too, that their source of greatest support was outside the university faculty; as a result, they were more careful to cultivate the outside group.

In modern form the traditional patterns of certification are all at present in contention. What is essentially new is the determination of academic professors, and their allies in the larger community, to minimize the influence that professors of education, State Department personnel, and other public school forces have traditionally held over the certification process.

I have perhaps stated the issue too simply. In some instances, quarrels ostensibly about teacher education serve to mask more fundamental conflicts over economic, political, racial, or
ideological issues. Furthermore, there are professors of the arts and sciences who warmly support education courses, and there are professors of education and public school people among the leaders in the movement to strengthen the teachers’ academic preparation. Moreover, in some institutions and states, the university faculties—academic and professional in concert—struggle to extend the institution’s autonomy against attempts by the public school people, the state Departments, and other interest groups to control its programs.

Yet it remains true that certification requirements rank high among the sources of hostility between professors of education and their colleagues in academic faculties. This should not be surprising, for the importance of these requirements on campuses throughout the country is enormous.

One would like to look at the education of future teachers in terms of a free market of ideas, and this I endeavored to do in my visits to teacher-training institutions during this study. But I came to the conclusion that such an inquiry lacks reality. The idea of state certification is so thoroughly accepted that I have found it hard to get a serious discussion of the question “What would you recommend if there were no state requirements?”

As for the attitude of the students taking state-required courses, I must report that I have heard time and again complaints about their quality. To be sure, by no means all students I interviewed were critical; so many were, however, that I could not ignore their repeated comments that most of the educational offerings were “Mickey Mouse” courses. There can be no doubt that at least in some institutions the courses given by professors of education have a bad name among undergraduates, particularly those intending to be high school teachers. To some extent, perhaps, this is simply because the courses are required. I am well aware, from my years of experience as a teacher of a subject required for admission to a medical school, that any required course has two strikes against it in the student’s mind. I am also aware that in some institutions the critical attitude of the students toward the education faculty is fed by the devastating comments they hear from certain academic professors.

The subject of teacher education is not only highly controversial, but also exceedingly complicated. The complexities are hardly ever acknowledged by those who are prone to talk in such slogans as “those terrible teachers colleges” or “those reactionary liberal-arts professors.” These slogans invariably represent a point of view so oversimplified as to be fundamentally invalid. This is not to say that either academic or education professors cannot be criticized. It is to say that neither side can be criticized to the exclusion of the other. In the course of my investigations, I have found much to criticize strongly on both sides of the fence that separates faculties of education from those of arts and sciences.

Earlier in this chapter I referred to the fact that the quarrel among educators had come to involve laymen. I had in mind, first of all, that teachers for our public schools are employed by local boards of education on the recommendation of the superintendent. Local boards are composed of laymen; therefore, these citizens are intimately concerned with the training of the teachers whom the boards employ. I had in mind also the fact that the freedom of the school board is limited by state requirements, which directly or indirectly are determined by laymen—the members of the legislature in each state. Indeed, the role of the state has been so important in shaping the development of teacher education that I am going to consider, in the next two chapters, first of all the way certification requirements are brought about in some of the more populous states, and then some of the policies that are actually employed today.

Unless one considers the relation of the state authorities to the school boards on the one hand, and the teacher-training institutions on the other, one is apt to miss what I consider a fundamental element in any plan for improving teacher education. The essential questions are: What role should the state play in the supervision of teacher education? And to what extent should universities and colleges be left free to experiment with new and different programs for educating teachers? My own answers to these questions will follow my report in Chapters 2 and 3 on
current practices. Thereafter, I shall devote the remainder of the book to suggestion for a fresh
approach to a four-year college program for teachers, and for improvements in current programs
for teacher education beyond college.

I am aware that many educators resent the idea that laymen should have anything to do with
education except to provide the funds. I do not agree with this point of view. What goes on in
schools and colleges is far too important to be left entirely to the educators. The layman as a
responsible member of a school board, a board of trustees, a legislature, or any public body, has
a vital part to play. The layman as a citizen who votes and pays taxes has every reason to make
his voice heard; as a parent and as an alumnus he should have concern with teacher education.
What he says, however, should be based on an informed opinion. It is with the hope of developing
such opinions that I have undertaken to write this book.

NOTE

1 The word “academic” has varying connotations; I shall use it to refer to those subjects traditionally taught in
faculties of arts and sciences.
9.3 Teacher education and the predicament of reform

Gary Sykes

A paradox lies at the heart of teacher education in America. For nearly half a century critics of all persuasions have scolded, even reviled, teacher education as a benighted and ill-starred enterprise, the very heel of our schooling system. Yet over this period teacher education has remained largely unchanged in important respects despite a variety of efforts at reform. True, the institution of teacher education has shifted from the normal school to the teachers college to the multipurpose university and the general educational level of teachers has risen. In 1961, nearly 15 percent of the teacher work force still held less than a bachelor’s degree, while less than a quarter had earned a master’s degree. By 1981, nearly one-half of all teachers held a master’s degree (or more) while the other half were at least college graduates. This may be counted true progress (although it paralleled a general rise in U.S. educational attainment over these two decades), but the debate over teacher education has never slackened, nor has the sense of malaise, of something badly amiss, lifted appreciably.

WHAT TROUBLES TEACHER EDUCATION

Teacher education involves a smorgasbord of enduring, unresolved difficulties along which critics in each era pass, making selections to fit the mood and spirit of the times. The central conflict has always involved the proper balance and relationship among what nearly everyone regards as the four necessary (and sufficient) components of a program: a strong liberal arts education, solid grounding in at least one subject area (particularly for secondary teachers), an introduction to education as a subject of inquiry and to an emerging science of pedagogy, and the opportunity to practice and experience teaching in a real yet controlled setting. So much appears self-evident as hardly to require elaborate justification for either individual parts or their constituency into a coordinated program of study and experience. Yet no practical synthesis has resolved the dialectics of this professional quadrivium, while the politics of teacher education have remained a zero-sum game featuring imperialist forays from the contending faculties of arts and sciences and of education.

An ambiguity of competence3 lies at the core of this territorial dispute. Teaching, like many undertakings, involves the employment of both special and ordinary knowledge, but stands apart in its reliance on the extraordinary use of ordinary knowledge. Teaching style appears to depend largely on personality and on tacit, idiosyncratic approaches to human relations. To many, teaching, like parenting, is a “natural,” “spontaneous,” “organic” human activity. Knowing subject matter and caring about children are the primary ingredients for success, around which some technical embellishments can marginally matter. Given this basic view, the notion of a “scientific basis of
the art of teaching," or of "sources of a science of education" seems dubious, a mystification of an essentially simple, universal activity.

By another view, however, teaching is an enormously complicated act whose full import has eluded the increasingly sophisticated methodological and conceptual tools of the social sciences. In the last decade, however, progress has been made and the rudiments of a paradigm have emerged, giving promise for the steady advance that characterizes the coming of age of a scientific field. The great hope—a scientifically validated knowledge base, an emergent science of pedagogy—seems less forlorn now, and the modest successes with applications suggest that stronger links between knowledge and practice are in the offing. But these steps are neither widely known nor credited, and the grounding of competence in science is a project still open to doubt and to counterclaims about the kinds of knowledge most useful to the aspiring teacher.

There is, too, in teacher education an unhappy legacy to live down. Visitors to college campuses have too often come away with a low opinion of the actual quality of faculty, students, courses, and standards in schools and departments of education. The paint has long since dried this portrait of mediocrity, of insipid if not anti-intellectual fare, of pseudo scientific “methods courses” and a “professional” jargon which apes social science. (Koerner labeled it “educanto.”) While the fraternity of teacher educators and researchers doggedly issues analyses proclaiming an imminent millennium if only the resources will be made available and the purposes properly fixed, the fleet of disconcerting reports sailing from the nation’s campuses has belied such optimism. Conservatives, perennialists, and devotees of the liberal arts have gleefully contributed to or seized on this literature to support their position, but a close look at reports on education usually uncovers an indictment of higher education in general, with the faculties of arts and sciences coming in for their share of blame and criticism. Yet teacher education’s position at the bottom of the academic pecking order is undisputed—a terrible handicap for those whose project is to raise up this enterprise via the fruits of science.

Complicating the indignities of internecine strife is the tenuous relation of teacher education programs to the schools. One dilemma here is common to professional education in all fields: to accept the conditions of practice, warts and all, preparing novices to fit a sadly imperfect status quo, or to take a critical stance toward current practice, imbuing the next generation with the need for change, with the imperative to make, not take, the role assigned. In teaching, though, there is evidence that suggests that socialization plays a far stronger role than formal training in shaping a teaching style. Research on the subject parcels formative influences into four sets of factors: the “apprenticeship of observation” that teachers undergo during their fifteen thousand hours of experience as students; the bureaucratic aspects of schools and the ecology of the classroom; supervisors’ and colleagues’ impress on teachers; and the impact of students as unintended agents of socialization. So, while the stance to be taken toward the schools is a genuine vexation to teacher educators, alternately provoking calls for closer collaboration or ringing manifestos to raise consciousness and stimulate reform, teacher education appears such a “weak treatment” as to make moot the argument.

As a practical matter, however, schools of education must nurture relations with the schools, which after all serve as the training ground for beginners, provide a shadowy extension of the faculty in the form of “cooperating teachers,” and supply the chief clientele for postbaccalaureate course work and the consulting that supplements faculty incomes. This relationship remains uneasy at best, with little coincidence of interests. School men complain about how out of touch university faculty are, students typically find only their practice teaching helpful, and the professors who know how it should be done express dismay at the gap between their ideals and the realities of life in the classroom. Each point of view is valid; but the means for reconciliation or accommodation have not emerged. Hence, these laments persist generation after generation.

The shifting tasks and protean agenda of the schools make the relationship between the universities and the schools as unstable as it is uneasy. The remarkable growth of the school
system has created serious strains, as educators have come to be expected to serve the full spectrum of the social structure. Likewise the transformation of the secondary school into a multipurpose social service agency has complicated the teacher’s role and expanded the domain of responsibilities to this larger, more diverse clientele. Underlying these changes, however, has been a deeper conflict over the priority of excellence, equity, or efficiency in the school’s mission. As the emphasis among these central cultural values has shifted from one era to the next, so too have the terms of criticism of the schools.

Teacher education is vulnerable in its own right to fluid social imperatives. While the training institutions must now prepare teachers for “the real world” of inner-city schools, for multicultural education, for educating the handicapped, for distinguishing the subtle bases for sex and race iniquities in their own and others’ behavior, for the computer revolution, and so on, they must also act affirmatively in hiring and admissions while maintaining high standards and producing a teaching elite capable of training the advanced manpower for mastery in world technology markets. Neither schools nor universities can serve up such a volatile brew. After a while, both institutions may be permitted a modest dispensation for hunkering down and resisting change.

The status, wages, and other valuables associated with teaching constitute a final difficulty for teacher education. Teaching has always suffered an equivocal status compounded of respect and disdain, reverence and mockery, as amply depicted in the writings of Hofstadter, Elsbree, Waller, Lortie, and others. Moreover, some evidence suggests that teaching’s occupational status actually declined between 1963 and 1980; according to one survey, teaching lost more ground than any other occupation ranked. One telling indication of this trend comes from a Gallup Poll item. When asked “Would you like to have a child of yours take up teaching in the public schools as a career?” 75 percent of those surveyed responded yes in 1969, 67 percent in 1972, and only 48 percent in 1980. To enhance the status and prospects of teacher education independently of the teaching occupation seems unlikely. Similarly, proposals to extend professional education for teachers run up against objections that few students would be willing to undergo a genuine training ordeal such as medicine requires or bear the costs of further schooling for the meager annual salaries and lifetime earnings teaching supplies.

That teaching is the closest thing to a mass profession may alone preclude a more elite status. Until the last decade, teaching regularly consumed 20 percent of the college labor market (35 percent of the market for college-educated women), and training institutions were hard-pressed simply to supply the requisite numbers, regardless of quality. Indeed, easy access to teaching has historically served as both a potent recruitment incentive for individuals and a guarantee that supply would not lag too far behind demand in a tight labor market. The route to sovereignty in the true professions of law and medicine—restricted access under the protective mantle of a meritocratic ideology—was never available to an occupation whose single, overriding imperative was growth.

TWENTY YEARS’ WORTH OF TEACHER EDUCATION

The oft called-for transformation of teacher education has failed through no lack of effort. Nearly everyone, it seems, has tried to reform teacher education; and our history is filled with task force and commission reports, with studies and recommendations, with association resolutions, government programs, foundation initiatives, legislation, and the rest. Teacher education has been the target for improvement both as an end in itself and as a means to effect other sorts of change in the schools and in the society at large. No assessment about what ails teacher education has yielded a consensus on what should be done, though, and the profession has proven vulnerable to a variety of enthusiasms, most of which has left little trace in their passing. A brief look at four reforms—The Master of Arts in Teaching, the Teacher Corps, Competency Based Teacher
Education, and recent state regulatory efforts—will serve to illustrate the trends over the past two decades.

**Recruiting an elite: the master of arts in teaching**

Beginning in the early 1950s and extending well into the 1960s, the Ford Foundation sponsored a bold new approach to teacher education. Over a fifteen-year period Ford committed some seventy million dollars in awards to over seventy universities to underwrite the establishment of a new teacher training program, the Master of Arts in Teaching (MAT). More specifically, Ford supported three types of programs: undergraduate training in a handful of liberal arts colleges, a five-year or fifth-year program, and the MAT. Most awards went to MAT programs to train secondary school teachers. These were alternatives, not sequels, to regular teacher education programs. They aimed at graduates of liberal arts programs and typically involved a summer school orientation on campus, then either a full- or half-time internship in a local school, supplemented by seminars and additional course work and perhaps a summer of course work after the internship. These postbaccalaureate programs resulted in a master’s degree and a teaching certificate; the five-year programs yielded only the certificate but were integrated with the undergraduate course of study.

The significance of these programs lay not so much in their innovative approach to the education of teachers (although the programs accommodated a variety of experiments) as in their impact on recruitment. Ford’s strategy was to enlist the elites among American universities to train a new cadre of teachers. Ford hoped that academically rigorous, selective programs at the nation’s best universities would set a new standard for teacher education and would lure the best and brightest among college graduates. At the institutional level the elite universities would influence their less prestigious brethren via higher education’s “snakelike progression” (David Riesman’s phrase), the status hierarchy impelling lesser institutions to follow the leaders. At the individual level, programs offered both an inducement and the removal of a disincentive: to study with the finest faculty and peers at the finest universities, and to avoid the dreariness of education courses. The grant strategy, then, called for bypassing the existing system in favor of an elite alternative, and implicitly viewed the status quo as part of the problem.

Additionally, these programs aimed to strengthen the ties of teacher training to the schools and to the liberal arts. The internship provided an extended yet controlled opportunity to work in classrooms under apprenticeship conditions—a genuine improvement over the usual, meager practice teaching experience. And, most proposals promised a renewed commitment to a liberal education through involvement of Arts and Sciences faculty in planning and implementing the program. Beneath the diversity in individual programs lurked the fundamental assumption James Bryant Conant made in his study of teacher education: that a strong liberal arts education, an extended, well-supervised practicum, and a modest dose of course work in education constitute the ideal.

Essentially a recruitment strategy, the MAT suffered some obvious limits as a paradigm of reform. First, the allure of the program consisted not in some technical breakthrough that the elites could model for others, but in the cachet associated with the places themselves. The glamor of Harvard’s simply being Harvard was not available in Pomona, Pierre, or Des Moines. Furthermore, the strategy relied on counteridentification with the status quo. Ford was consciously elitist in culling universities east of the Mississippi and north of the Mason-Dixon line that represented a liberal arts tradition very different from that of the mainline teacher training institutions. The aim, in part, was to enrich the pool of liberal arts graduates willing to teach by skirting the standard course of teacher education. The immediate appeal of such a strategy to education school deans and professors was not readily apparent.

The MAT failed to spread much beyond those few institutions that received Ford funds. Evidence
on numbers completing MAT programs is fragmentary, but one study reported that in the three-year period 1961–1962 through 1963–1964, 4,114, students graduated, as compared with an annual production figure in those years of some 200,000 new teachers. MAT programs, then, accounted for less than 1 percent of the nation’s new teachers. That only a handful of MAT programs are left testifies to their tenuous hold in the elite universities. Declining student enrollments and the teacher surplus of the 1970s hastened their demise. But even though the MAT programs were lively and exciting while they lasted, and anecdotal evidence suggests they were successful in attracting bright liberal arts graduates to teaching, the handwriting was on the wall from the beginning. Teacher training had little enduring appeal for either liberal arts professors or faculty in graduate schools of education who wished to get on with training administrators and researchers. The mission of training teachers never gained much legitimacy, never secured core support, never engaged the faculty in the crucial roles of supervising interns, spending time in the schools, or conducting the companion seminars and courses. Teaching’s low status ultimately confounded the attempt to enlist higher education’s elite, who returned gratefully to traditional pursuits after this brief flirtation with teacher training.

Welcoming the great society: the teacher corps

Prior to the 1960s, the federal government was little involved with teacher education, but in the late 1950s it began what amounted to a sizable investment in the 1960s and 1970s. National defense provided the rationale. Initial government ventures aimed chiefly at improving teachers’ subject matter competence via in-service activities. The programs operated through the existing institutional structure and eschewed fundamental reform. But as the conservative tenor of the 1950s gave way to the social activism of the 1960s, the federal government sponsored a range of more far-reaching programs, often in conjunction with the decade’s major equity mandates. The government initiated or intensified training expenditures in vocational, compensatory, and higher education, in special education, and in bilingual education. Much of the funding went to teachers’ in-service; but a number of programs were aimed at preservice training as well. In 1967, Congress passed the first piece of comprehensive legislation aimed at the development of educators, the Education Professions Development Act (EPDA). The act consolidated several existing program (e.g. Teacher Corps) and spawned twenty-five programs of its own. In its nine-year life (1967 to 1976), these programs accounted for expenditures of $781 million on a wide range of innovative projects. Over these decades Washington controlled the agenda for reform and set a brisk pace. Directly or indirectly the federal government provided the funds and mandates, the strategies, the leadership, and the influence networks through which flowed a powerful current of reform and innovation. By 1981 forty-three federal programs expended nearly $6 billion on personnel development with nine formula grant programs accounting for 90 percent of this total. (The Reagan administration, however, has eliminated or consolidated and reduced the budget of many of these programs.) No other development in this period so profoundly influenced teacher education as this centralization of reform. The Teacher Corps represents a small but significant piece of this history, and is worth examining both in its own right and for its lessons about federal programmatic reform.

Created in 1964, the Teacher Corps was touted initially as a domestic Peace Corps. In its early years the project supported a two-year internship for liberal arts graduates who wished to serve in low-income schools. The original purposes included strengthening the education of disadvantaged children, attracting and preparing persons to teach such children through coordinated work-study experiences, and encouraging colleges and universities, schools, and state departments of education to work together in improving teacher education. The program’s rationale
stressed that there are critical differences between the skills, attitudes, and experiences required to teach successfully in low-income schools and in middle-class schools. The corps sought to recruit idealistic young people and to provide them with mediated entry to teaching in schools where they were most needed. The typical program involved thirty to forty liberal arts graduates (interns) and five experienced teachers who acted as team leaders. Following a summer preservice training program at a college or university, each team was assigned to a school serving a poverty area. Interns spent some 60 percent of their weekly time in schools, 20 percent in academic work at the university, and 20 percent in community activities. This two-year course resulted in certification and a master’s degree.

Due to its entrepreneurial leadership, the Teacher Corps enjoyed a chameleonlike existence over its sixteen-year history. Program guidelines emphasized a series of vanguard themes, including, “performance based teacher education, training complexes, portal schools, research adaptation, education of the handicapped, multicultural education, youth advocacy, basic skills, organization theory, and models of teaching.” When the teacher shortage of the 1960s turned into a teacher surplus in the 1970s, the program secured congressional authority in its 1974 reauthorization to work with in-service teachers, and in 1978 extended the time span of local projects from two to five years. Initiated as a service program, the focus shifted after 1975 to a demonstration strategy for training and retraining experienced teachers and teacher aides.

The Teacher Corps had undergone seven major evaluations over the years, and its effectiveness as a reform strategy is unusually well documented. During its ten years as a service program, the Teacher Corps, like the MAT programs, proved an effective recruitment strategy. Evidence from several projects in the early program cycles suggests that the corps successfully attracted bright, change-oriented college graduates. With backgrounds in the liberal arts, the early interns displayed academic aptitudes above those of graduate students in education (but still below the median of all graduate students). Initially, the Corps attracted white, upper middle-class youth, but determined efforts to recruit minorities increased their representation in later cycles. Imbued with the spirit of the times, the new recruits were more change-oriented, politically liberal, independent, and aggressive than their veteran counterparts. However, those drawn to teaching exclusively by the Teacher Corps program were also most likely to drop out. While a majority of interns went into teaching upon graduation, most did not anticipate a career in the classroom but intended to take on other roles in education. So it appears the Corps attracted a new breed of teachers but could not hold them long in the classroom.

Teacher Corps was less successful in altering institutional patterns within the schools, colleges, or universities. The program’s early rhetoric urged the intern teams to serve as change agents within the schools, but the sources of resentment and resistance proved too strong. Veteran teachers regarded interns merely as apprentices useful in assisting with normal duties. Filled with the program’s reform rhetoric the interns sought greater influence and often threatened the regular teachers with their radical ideas. The intern status could not easily accommodate the dual roles of change agent and apprentice. Interns possessed neither the technical knowledge nor the formal position to support their posture, so the schools shrugged them off. Some interns became radical and alienated in the process, while others were co-opted.

Colleges and universities, too, made few concessions to the program and resisted a more enduring involvement with the schools. Teacher Corps projects stimulated the addition of some new courses and raised consciousness about the special problems of teaching in low-income schools but failed to promote closer ties with higher education. The interns were more critical of the universities than any other aspect of the program. They found their courses irrelevant and judged that their professors knew little about teaching the disadvantaged and were less academically qualified than their undergraduate professors. The faculty acutely felt their inadequacies in educating the interns but themselves had no contact with the schools, no relevant, special knowledge to impart, and no solid commitment to the projects.
Teacher Corps projects also had difficulty overcoming the social isolation between schools and universities and could not supply the incentives for true collaboration. Vested interests within the higher education community resisted new missions, new priorities, or any reallocation of resources. When changes occurred, they tended to be superficial add-ons. Boundary-spanning personnel—the project director, team leaders, or unusually dedicated university faculty—sometimes created effective partnerships, but, “the hoped-for ‘hybrid’ professional, trained in the social sciences but concerned with the application of knowledge to educational practice, seldom appeared.”

In short, the institutions operated under different incompatible incentive systems and had independent publics and resources. The schoolteachers were precariously trying to maintain daily teaching schedules with inadequate resources, often in the face of challenges from both students and the community. They were not primarily responsible for training and resisted being used as laboratories unless they had been provided with assistance or other benefits. University professors were oriented to an academic status system and were insulated from the operational pressures of school teaching and from the unruly or dull classrooms. Therefore, they could not provide the practical guidance and necessary leadership that interns needed. The interns were trapped between the university, which controlled their professional certification and the schools, which controlled their professional experiences.

Ambitious in scope, complex in conception and execution, the Teacher Corps took on a number of long-standing problems plaguing both teaching and teacher education: the difficulty of recruiting talented college graduates to teach in low-income schools, the lack of attention to pedagogy suited to disadvantaged and minority students, the remoteness of colleges and universities purporting to train teachers from the schools, the strong resistance to change in the public schools themselves. Like other helping professions in the 1960s, teaching proved vulnerable to government intervention on behalf of society’s neglected and oppressed. The profession could not resist these external pressures; but in a decentralized system and without a consensus, federal authority was not strong enough to affect institutional patterns and reward systems. Working within the existing system, subject to the constraints of special interest politics and of organizational inertia within the schools, the program had but modest long-term impact.

**Quest for certainty: competency based teacher education**

In the late 1960s a number of themes in our political culture converged in a reform known as Competency Based Teacher Education (CBTE). The movement toward this reform drew support from the U.S. Office of Education, from several state departments of education, from the American Association of Colleges for Teacher Education (AECTE), from a handful of vanguard universities eager to innovate, and from a group of educational researchers. These groups stimulated intense interest in CBTE for a time, but the reform failed to attract widespread support and faded away in the face of retrenchment pressures in the 1970s. CBTE, however, represents a persistent strain in American education: a powerful yearning for method, for system, for certainty. Moreover, the fact of this reform illustrates education’s difficulty with establishing a knowledge base. It is, then, worthy of attention beyond its impact.

Competency Based Teacher Education was an attempt to gain technical control over the preparation of teachers, to ground a professional curriculum in science, and to establish its measure for purposes of public accountability. The method, behaviorist in spirit, had the straightforward appeal of an engineering feat. Steps in the process called for, first, the decomposition of teaching into a set of discrete competencies, empirically validated through their connection to learning outcomes; then development of a training program within which students would learn the
appropriate behaviors, via practice and coaching; close evaluation of students to determine their mastery of the competencies, with additional training prescribed for those who required it; and finally, certification based on mastery of the mandated competencies.

Proponents of this approach did not claim that teaching is simply a finite bundle of skills, nor did they deny that teaching is an artistic activity involving improvisation. Rather they argued that effective teachers exhibit skills that can be precisely identified and transmitted. The business of an initial training program is to provide such skills to novices as the foundation for development of a mature teaching style. This rationale at once supplied an implicit critique of current practice, a powerful appeal based on culturally authoritative symbols, and an orderly agenda for progress.

Status-quo training programs suffered, according to competency advocates, from two major shortcomings: a failure to base the professional curriculum on empirically validated knowledge, and a lack of precision and specificity in setting forth the skills of teaching to be mastered. Teacher education was at once too abstract, too impractical, and too trivial. Coursework failed to connect theory to practice, while methods courses deserved their ill repute as whimsical collections of gimmicks. A competency-based approach would remedy these defects through introduction of scientific rigor. Teaching would be systematically analyzed, and its core elements extracted, then validated through research. The result would be a training program organized around a set of competencies enjoying science's imprimatur.

CBTE as a rallying point had a number of obvious appeals, the primary one being that it promised to establish the intellectual legitimacy of teacher education through a grounding in science. In an era marked by increasing accountability demands on public service providers, CBTE offered the means and a commitment from educators for such an accounting. A fully developed program would utilize social science's most powerful and sophisticated technology—testing—to monitor progress, to diagnose difficulties, and to certify graduates. Professional educators would have the tools to gauge student progress, to prescribe extra and remedial work, and to identify those who lacked all aptitude and should therefore be counseled out of teaching. Rigor, precision, and control: these were the virtues around which to reconstitute a course of training.

CBTE possessed a further virtue as well. The design of teacher education around a set of competencies was a development largely internal to schools and departments of education, strengthening their claim to professional standing within the university. CBTE was a technical reform involving an orderly agenda of research and development. If the movement's leadership could establish the paradigm's power and gain a consensus within the educational community on its general outline, then widespread, concerted efforts could go forward and "normal science" (in Thomas Kuhn's sense) could take shape. Furthermore, a technical breakthrough would strengthen the hand of educators seeking to secure greater resources for pedagogical education. CBTE's proponents recognized that at the time there was no set of empirically validated, generic teaching competencies, but hoped that a sustained, united commitment to the approach from the profession would gradually yield such knowledge.

Creating competency programs required a substantial initial investment of faculty time and cooperation, but in the late 1960s several universities undertook such efforts, stimulated by modest funds from foundations and the U.S. Office of Education (which expended some $12 million, mostly for conferences, dissemination, model building, and the like). Some schools, including Weber State College, the University of Houston, Toledo University, and Florida International, recast their entire programs; others, notably Brigham Young University, the University of Texas-El Paso, and Western Washington State University, established alternative programs. There was never a careful account of how many institutions participated, but a 1972 AACTE survey of 783 institutions turned up 125 that claimed to have such programs, with 366 others in the developmental stage. (What "developmental stage" meant, though, was not clear.) Another AACTE publication provides details on seventeen programs located in thirteen institutions, with the range of effort from modest experiments to total conversion. The slender record suggests
that the reform stirred up enormous interest, spawned a large volume of talk and publication, but had near negligible impact in the universities themselves.

Competency education’s difficulties are instructive both for the technical problems that proved insurmountable and for the opposition that the reform provoked. The yearning for a knowledge base could not compensate for its absence. In the face of multiple conceptions of teaching, multiple interpretations of classroom realities, and multiple educational aims, the hoped-for consensus on a unifying paradigm never emerged. Without the discipline of relatively unambiguous, fixed ends, the technical project of securing the means-ends relationship could not advance. And the attempt to validate teaching competencies through their association with student outcomes soon provoked challenges on grounds: the evidence was impeachable and the research community divided on its worth.

Furthermore, the notion of a teaching competency itself proved more troublesome than helpful. There was no agreement on whether a competency was big or small, referred to “knowing how” as well as “knowing that,” or was subject-specific or generic. The effort to provide behavioral specificity yielded nearly a thousand competencies by one reckoning. To avoid the traditionally loose, abstract, and behaviorally unanchored accounts of teaching, competency logic drove to a ludicrously atomized conception which in the same manner failed to provide guidance to teacher training. Just as overwhelming was the task of assessment. Reform rhetoric promised both accountability and individualization via a measurement and tracking system to chart each student’s progress toward mastery of hundreds of competencies. But the measures were fallible to nonexistent, and the management burdens enormous. In short, the behaviorist approach, so appealing in its promise of rigor, system, and method, could not carry the intended freight.

As the CBTE vanguard grappled with these problems, opposition also took form. Humanists quickly became suspicious of competency education on a number of counts. Harry Broudy, for example, worried that the approach reduced teaching to the imparting of information and thus sacrificed its other modes and dimensions. He argued that teaching involves more than skillful behavior; that teachers must develop understanding of their actions as educators and must be able to consider ends as well as employ skills. If teachers were to be more than craftsmen following set routines, asserted Broudy, then their education must include theory and must aim at creating a capacity for reflection and flexible action. Yet he saw little appreciation for this in the competency approach. In his view, CBTE actually threatened to deprofessionalize teaching by turning out proficient technicians, not full professionals.

Yet another critic feared a bias against intellect, against what was “merely academic.” He first asked, “Does competence based education reduce the teacher to a coach merely drilling people to pass exams? Does the competence approach kill all true education or deeper thinking?” Not necessarily, he thought. A more moderate rhetorical question expresses his view: “Does competence based education lead students and teachers to be predominantly pragmatic? Not simple-minded or trivial or blindly mechanical, mind you, but does it lead to a slight narrowing in the range of human styles, away from creativity, intuition, play, humor, and purely disinterested curiosity? Is the spirit of competence, in short, the spirit of instrumentalism?” Thus did humanists come to characterize competency education as at worst illiberal, anti-intellectual, and technicist, and at best merely an admonition to teacher educators to think harder about what they were doing.

CBTE was a bootstrap operation by déclassé teacher training institutions to gain credibility and prestige in an era of accountability, a technical reform internal to the school of education, whose rhetoric drew upon powerful cultural themes. Its proponents hoped this sort of inexpensive, nontaxing innovation would support their argument for a truly professional school and for more “life space” in the university. However, the requisite technical knowledge never appeared at the party thrown in its honor, and program conversion along competency lines proved more expensive than anticipated. One calculation, likely an underestimate, placed the cost at $5–6
million per institution, with a total system cost over twenty years of $100 million. During CBTE’s brief period of fashionability, most institutions found it cheaper to adopt little but the rhetoric.

Faced with philosophical and political opposition and fraught with technical difficulties, this reform’s liabilities outweighed its benefits in the eyes of most teacher educators. Championed by lesser institutions, CBTE failed to enlist opinion leaders in higher education’s pantheon. It was, in short, a very shallow ripple on a large pond, one that illustrated the difficulties in establishing a knowledge base for teaching and the danger in premature sponsorship of an ill-conceived technical reform.

**Crisis of confidence: state regulation of teaching**

As foundations, universities, and the federal government have all attempted to recast teacher education in various images, so too have state policymakers intermittently taken an interest. Their tools, however, have been regulations rather than programs, funds, or new knowledge, and the history of state regulation reflects teacher education’s uneasy regard among the public. State certification and licensing laws have the dual potential to protect the public interest via standard setting and to enhance professional status by restricting entry and requiring special courses of study. The legitimacy of such laws rests on the public’s perception of an equivalence between these functions, but the relationship is weak. Without scientific breakthroughs or potent technologies, teacher education must rely to a considerable degree on trust that its mission is valuable and useful. Perceptions that the schools, hence the teachers, are failing threaten this trust and impel state regulation as protection from, not protection of, professional autonomy.

Over the decades, the states have tirelessly tinkered with the certification law. Early on, many states and localities used literacy tests to screen candidates. In the 1830s, for example, Illinois state legislator Abraham Lincoln voted in favor of a teacher exam, which became common by the century’s turn. But as schooling levels rose and normal schools sprang up, states began to require years of schooling, then courses in education for certification. By 1940 the course requirements approach had largely superseded examinations, with additive reform—more years of schooling, more required courses in education—the progression thereafter. Twenty years later, however, Conant reflected much public opinion in labeling such policy bankrupt. The low repute of education courses made their mandate through state policy an embarrassment. States, it appeared, were conspiring with the “education establishment” to require a fraudulent set of courses that had failed to demonstrate their worth.

This mounting criticism posed a crisis of legitimacy for teacher educators. Their clients (the students) expressed great dissatisfaction, Arts and Sciences faculties decried the wasteland of teacher education, and policymakers were becoming uneasy. However, two events forestalled action. First, the teacher shortages of the 1950s and 1960s turned to a surplus. Enrollments declined in teacher education, and few new teachers entered the schools. Concern consequently shifted from preservice education to renewal of an aging work force already in place. And, second, the 1960s’ preoccupation with equity and civil rights intervened to shift the ground of criticism and the agenda for public policy. Relevance and rights, not rigor, became the watchwords, and the critiques of Conant, Koerner, and Silberman for the moment lost their salience. The locus of reform shifted, as well, from the state to the federal level and over the next decade state policy took shape largely in response to the cascade federal initiatives.

Enrollment declines and the social ferment of the 1960s and 1970s merely deferred the fundamental dissatisfaction with the quality of teacher education expressed earlier. By the mid-1970s, public worry over the test score drop, over reports of lax discipline in the schools, and over a general decline in standards was paramount. The academic adequacy of teachers became an issue as the press reported cases of teachers who wrote and spoke ungrammatically and who could not spell. The suspicion also took hold that some training institutions, faced with
enrollment declines, had lowered entry standards to maintain their share of students. The
demand for quality control led to the reintroduction of testing in state after state, so that at present
thirty-six states have mandated some form of test for entry to a teacher education program and/or
for certification.37
Some jurisdictions have extended their concern for teacher quality further still. Georgia sends
observers into beginning teachers’ classrooms to rate their performance on fourteen teaching
competencies. South Carolina has required increased practice teaching, more observation and
evaluation of teachers, and additional credits for recertification. Oklahoma’s new Bill 1706 similarly
mandates more clinical fieldwork and an entry-year internship during which a committee
composed of a principal, a consulting teacher, and a teacher educator regularly monitors the
first-year teacher and recommends either certification or further supervision at year’s end.
The states have emerged as standard bearer for teacher education. While the older “approved-
program approach” to certification—i.e. graduates of approved programs were certified simply
because they were graduates of approved programs—implicitly reposed confidence in the training
institutions, this new body of law regulates teaching in the name of public protection. Through
tests, the states have extended their influence indirectly to the curriculum of teacher education,
as training institutions must now ensure that their graduates can pass the tests. States are no
longer willing to trust the profession to set standards. They have intervened firmly and in the
name of accountability. To some extent, teacher education’s interests have benefited from the
new legislation which they have helped shape, but in many respects state regulatory action
reflects the lack of public confidence in teaching and the loss of esteem for teachers. By
emphasizing basic skills and general rather than professional knowledge, the tests themselves
are demeaning and seem to imply that any reasonably bright college graduate can teach.
For years teacher organizations have pressed a professional governance model on state
policymakers, and a half dozen states currently support professional practice boards with
teacher membership. But vesting regulation of the teaching occupation in its practitioners enjoys
no widespread support, and the unions’ use of professional rhetoric and strategy is not credible
anywhere. Unions exist to protect the rights of their members; but the rationale for professional
control, especially among public employees, rests not on an assertion of rights but on claims of
technical expertise and of the public interest.
The states, though, can do little else through a regulatory approach than set minimums and
thereby symbolize a concern for standards. Though the most academically deficient will be
denied access to teaching, at the program level little is likely to change. These recent state
responses fail to address one of the fundamental dilemmas facing teacher education: that with-
out additional resources, it cannot demonstrate its worth; yet without such a demonstration, it
cannot secure additional resources. This dilemma ultimately frames teacher education’s relation
to the state and makes vivid the crisis of confidence.

Prospects for an enlightened future
These various efforts over the years to reform teacher education achieved some limited and
temporary success, but could not effect a thoroughgoing transformation. The enterprise as a
whole seems fixed by a range of institutional, demographic, and economic forces at an
unacceptably low level of quality, incapable of setting and enforcing—or even of articulating and
projecting—high standards. Invidious distinctions of status among the institutions of higher edu-
cation, among departments and schools within the university, and between the universities and
the schools frustrate the search for a common cause. Despite decades of earnest labor and
some progress, no research paradigm has emerged to order the pursuit of knowledge and no
cognitive base organizes, unifies, and legitimates the professional curriculum. Inevitably the
mission is shortchanged. Teacher education is underfunded and lacks institutional “life space.” It is
a small, old outboard propelling a very large cabin cruiser through the water at an unsurprisingly slow rate.

Several recent developments have complicated these woes. Unionism has replaced professionalism as a strategy for advancement among teachers. An overlay on existing status tensions, unionism has further estranged teachers from teacher educators in terms of their organizational interests and public posture, rendering even more suspect the rhetoric of professionalism. And, as enrollments in teacher education dropped 50 percent between 1972 and 1980, thereby threatening the survival of many programs, coping with decline superseded programmatic reform. Retrenchment proved inhospitable to the quest for excellence. Simultaneously the states intensified their regulation of teacher education, exposing its vulnerability to external control. This policy development revealed teacher education's inherent weakness in relation to the state: the public confidence required for control over teaching to be vested in teacher education institutions has been based more on inattention than approval.

Most friendly critics appreciate that reforms of teacher education stand little chance unless linked to changes in the schools, in the teaching occupation, and in the policy framework shaping the whole enterprise. They emphasize that teacher salaries must be higher, that working conditions must better support teachers, that teaching must attract and hold more academically able recruits, and that state policy—particularly allocation formulas to the universities—must supply more resources.

If the past is prologue in teacher education, then widespread, comprehensive reform is unlikely. The prospect of converting teacher education to a postbaccalaureate program (whether integrated with the undergraduate curriculum or not) appears slim. To require an extended program of training for all new teachers without a corresponding increase in the rewards of teaching is not feasible: market pressure will continue to dominate standards. Likewise, no major reallocation or infusion of resources to teacher education is likely. The training venture has not gained sufficient warrant for this, in part because its rationale is derivative: teacher education exists to improve teaching. With ever-present arguments that both teaching and teacher education are underfunded, and without an impressive demonstration of the latter's potency, policymakers will most often direct funds to teaching itself. Finally, social science knowledge is unlikely to rationalize a technical transformation of the professional curriculum. No paradigm orders inquiry in education, no "sciences of the artificial" nor eclectic arts conjoin basic knowledge and design; rather, the technical base grows fitfully and in small increments.

Short of ambitious reforms, though, teacher education has several modest prospects. Both the MAT strategy and the Teacher Corps demonstrated that special programs can enhance status, supply an esprit otherwise lacking, and recruit able college graduates despite teaching's low pay. For a limited number of prospective teachers a selective postbaccalaureate program highly regarded by the university and by the community will be attractive. The MAT approach never received much trial in the mainline institutions, yet might well serve as an alternative on more campuses.

Efforts to extend training into the first year of teaching point to another promising trend. State-mandated induction or intern programs such as Oklahoma's join the university and the schools in providing more support, supervision, and evaluation for first-year teachers, a step intermediate to and less costly than a full extended program. Intern programs have several virtues: they are job-related, do not defer income for young teachers, can involve experienced teachers in passing along their lore, and provide a performance base for certification. The Teacher Corps experience underscored the importance of boundary spanners between universities and schools, and the new state mandates may help provide a framework within which such positions will develop. They appear crucial to effective collaboration.

Finally, the gradual accumulation of usable pedagogical knowledge provides a more spacious avenue for technical improvements in the professional curriculum. For some time advocates have
faulted the training programs for failing to stay abreast and failing to use the best available knowledge, arguing that the translation and use of knowledge, not its quality or quantity, are the fundamental problems. Progress in the coming decades, then, will take the form of better knowledge use in the training program, and stronger connections between research and training.

The neglected dimension

Interpreted in broad outline, teacher education appears trapped in a force-field admitting only small movements in any direction. Yet other histories and interpretations are available. This broad interpretation of teacher education’s status omits consideration of the individual institutions where stories of success and failure, triumph and tragedy, progress and stasis have played out over the decades. A bit of determinism often accompanies history as global sweep, denying the choices and maneuvering room actually open to individuals. But let us step down from the slow movements of history and the grand strategies of reformers to the prospects for renewal and excellence in particular institutions and glimpse other possibilities.

Worry over what is lacking in teacher education often centers on such things as funds, status, standards, life space, and knowledge, with corresponding attention to these resources in reform proposals. Yet this emphasis on the instrumental neglects an important dimension in the lives of individuals and institutions. What is most fundamentally missing in teacher education is both a conception and conviction of its value. The enterprise of preparing teachers in our society is not esteemed, and the consequences of this lack of esteem are devastating. Without sufficient caring we have no appreciative framework for teacher education, no shared conception of quality, no capacity to recognize or vocabulary to describe excellence, nor occasions to celebrate it. The process of educating teachers is essentially invisible, a sure sign of its undervaluation in our culture.

The outward manifestations of this problem should now be clear, but there is a toll on the inner life as well. Every professional practice requires a discourse continuously enriched through reference to transcendent ideals. Central to human services is a sense of mission powerful enough to inspire and sustain, to give meaning and significance to the work. Without occasions for pride and a sense of connection to important values, the vicissitudes of human service work can be great. As any teacher will acknowledge, working with others has both a light and dark side, an inevitable feature in the pursuit of ideals that at once compel but admit no easy realization. Teaching can provide joy and fulfillment, but can be frustrating and enervating, too. Visions of excellence nourish the light side, enabling buoyancy and resilience. Their absence leads to low morale, failure of nerve, loss of expectations.

Missing from the rhetoric of reform in teacher education is much attention to this expressive side, to the inner life of the enterprise. Consider, by contrast, the emphasis in some recent writing on management that hails the creation of corporate cultures as a hallmark of excellence. In these accounts of successful businesses and business leaders, it is not technological breakthroughs or rational management schemes that matter, but attention to the human side of enterprise. The corporate exemplars stand for and communicate a set of values through rites and rituals, organizational sagas, and proud traditions filled with heroes and champions. The new language used to describe corporate life is remarkably primitive, smacking more of Margaret Mead on Samoa than of Harold Geneen at ITT. It is an anthropological language redolent of mythology and symbolism, a language appropriate to the centrality of values.

"Companies succeed," claims one observer, "because their employees can identify, embrace, and act on the values of the organization." So, too, do programs of teacher education, yet preoccupations there are unrelievably literal, instrumental, and parochial. The rhetoric is too often plaintive, too seldom inspirational. Needed is not another six-point program of reform complete with arguments pro and con and steps toward implementation, but eloquently rendered
visions of excellence. To repeat: what the leadership has most sadly neglected in teacher education is not resource calculations or the mechanics of reform but reasons and ways to care.

This concern for value, for meaning, is no mere froth on the bracing brew of hard-headed practice. Rather it is something more serious, more fundamental to the life of an institution. Although I have argued that the larger predicament of teacher education is in a sense tragic—the show must go on but with no promise of greatness on a grand scale—there is room for affirmation and progress at any institution that prepares teachers. But the starting point for those who are interested—the university president, the dean, the professors—must be with the value of the enterprise itself, even in the face of public indifference, narrow institutional confines, and resource poverty. Teacher education needs its heroes, its sagas, its proud traditions that embody and convey what is valuable in the undertaking. This, I judge, is the place to start.

NOTES

2 For this phrase and the related ideas, I am indebted to David Cohen. See his unpublished manuscript, “Commitment and Uncertainty,” May 1982 (available from D. Cohen, Harvard Graduate School of Education, Harvard University, Cambridge, MA 02139).

14 For example, Stone, ibid., p. 158, reports that in 1961–1962 and 1962–1963, 2,187 teachers successfully completed experimental programs, of whom 78 percent were teaching in the subsequent year. During the same period 16,117 completed the conventional program in these same institutions, of whom only 49 percent were teaching in the following year. He further reports that a six-year follow-up of University of California-Berkeley MAT graduates, 1956 to 1962, reveals a sizable number still teaching, with a similar report from Harvard in the first decade following World War II (under President Conant, Harvard had established its MAT program before the Ford Foundation became involved).

37 J. T. Sandefur has been tracking the development of teacher competency tests. He reports that the turn to teacher tests began in 1977, and that of the 36 states involved, 21 test or plan to test applicants for
admission to teacher education programs, while 28 states test or plan to test prior to certification. Ten states now also require some on-the-job assessment, usually a one-year internship or induction program for beginning teachers. See J. T. Sandefur, “Teacher Competency Assessment Plans ‘Little Short of Phenomenal’ ” (Washington, D.C.: AACTE Briefs, November 1982).

Part 9
Commentaries
This is an interesting group of papers, which tackle some of the thorniest issues that bedevil teacher education. The long history of teacher education has been beset with debates about how it should be organized, whether it should stress content or pedagogy, whether it should be professional or vocational, and even whether it is necessary at all. In the nineteenth century, when the first teacher training institutions and normal schools were established, teaching was a humble occupation indeed. Itinerant teachers were commonplace, as were schools managed by anyone with a bit of book learning. At the beginning of the twentieth century, there was a concerted effort by the various professions to set standards for entry, to establish professional schools to prepare those who would qualify for the profession, and to administer entry tests to the profession. So, while it was possible in the nineteenth century to read for the bar or to become a doctor by apprenticeship, those informal routes into the legal and medical professions were eventually closed, and admission was restricted to those who had taken a specified educational program and passed their qualifying examinations. In medicine, of course, the requirements for admission to the profession included a clinical training period as well.

Education stood outside that paradigm. As William S. Learned, William C. Bagley, et al., show in what came to be known as “the Learned report,” schools of education were usually seen as multi-purpose; their students might be preparing to teach, or they might not. In any case, schools were usually so eager for teachers that they were likely to hire someone with no training in a normal school. The entirety of the Learned report, commissioned by the Carnegie Foundation, was supposed to do for teacher education what Abraham Flexner’s report had done for medical education. Learned and his colleagues argued that normal schools should evolve into single-purpose institutions to educate future teachers; they thought that the normal schools should be the education profession’s equivalent of law school and medical school, with the same fixity of purpose and the same high prestige. In their view, the curriculum for future teachers should combine content and pedagogy; every course would demonstrate how to teach subject matter to students, regardless of their grade. At the end of a four-year prescribed course of studies, marked by a case-based approach and practice teaching in training schools, future teachers would be examined for their readiness to teach. Learned’s goal was not to “vocationalize” teacher training, as the entry to this section says, but to professionalize it. Interestingly, David Imig and Scott Imig wrote about the farsightedness of the Learned report in Change magazine, calling it “a vision delayed.”¹ The Imigs suggest that teacher education might have been transformed—and the current debate obviated—if education leaders had taken seriously Learned’s ideas and created truly professional preparation programs for teachers. As it happened, however, the normal schools evolved into comprehensive colleges, leaving open the question of how best to train teachers and whether to train them at all.
Steven Weiland’s paper wrestles with the age-old problem of making sure that future teachers are liberally educated. He writes at a time when leaders of higher education seem less sure than ever about what a liberal education is and how to teach it. In addition to the uncertainty introduced by postmodernism, relativism, and various other -isms, there is the upsurge of vocationalism among college-age youth. Anyone who reviews statistics on college majors cannot but be struck, and possibly depressed, by the decline of majors in traditional liberal arts subjects and the increase in majors in business and other fields that promise immediate economic payoff. There was a time, though it now seems like ancient history, when academicians had a shared understanding of the meaning and purpose of the liberal arts. That was before the Culture Wars and the Canon Wars. Now, as Weiland shows, we must all engage in a sort of academic archeology, trying to figure out or remember what it is, what it was, what it should be, why it matters. Weiland suggests that teacher education might profitably “move . . . toward liberal education” and that students will thereby develop “enduring intellectual interests,” but it is not clear how this will happen in the current situation of teacher education, what might be added, what subtracted from the curriculum.

Frank B. Murray maintains that “teaching by second nature” is a skill that many people have, without any specific training or preparation. They just know how to do it. He also persuasively argues that this kind of teaching is usually inadequate; he draws a useful distinction between a “naive” teacher and an “educated” teacher, with the latter having a deeper understanding of how students learn and what their mistakes mean. As I read his essay, I thought of certain young people I know who had a superb education, decided to teach, and found that they were unable to get across what they wanted their students to learn. They had a secure knowledge of their subject, but were unable to figure out how to teach it in ways that adolescents understood.

The most surprising paper in this section, from my point of view, is the one written by Mary M. Kennedy, Soyeon Ahn, and Jinyoung Choi. The authors set out to compare the value-added by different educational backgrounds, as reflected in students’ learning gains. They looked at variations in what teachers had studied before they became teachers and sought to compare the value added by the following kinds of knowledge: pedagogical knowledge, pedagogical content knowledge, and content knowledge.

One would have expected that a paper written by researchers at a major school of education might conclude in a defense of pedagogical studies. But this was not the case. Indeed, the authors arrived at some interesting and unexpected findings. One is that individual courses, whether in mathematics, mathematics education, or pedagogy, have positive effects, but pedagogical courses have a smaller effect than the other two domains. Also, advanced degrees in education are negatively correlated with student achievement, but advanced subject-matter degrees in mathematics have a positive effect (except in elementary school). The authors caution that these findings derive from a single data base.

When they looked at evidence for what they call “the Bright, Well-educated Person hypothesis” or BWE, they found that BWE teachers from highly selective colleges were associated with higher student achievement; but when they looked at schools where students were randomly assigned to teachers, the BWE teachers did not achieve good results with their fifth-grade students. The authors then looked at Teach for America teachers as examples of BWE teachers. They did indeed find gains in student learning for the BWE who were TFA (there is a certain resonance to those acronyms!). However, their conclusions were confounded by the fact that BWE teachers often did have pedagogical knowledge that they gained in their training program or in graduate courses, and the comparison group of teachers had a wide range of educational backgrounds. In short, they found it nearly impossible to conclude that they had truly compared the raw
educated talent of a pure BWE—untouched by pedagogy—with teachers who had been thoroughly immersed in pedagogical training. Ultimately, the authors conclude that all three domains of knowledge—mathematics (course content), pedagogy, and pedagogical knowledge (mathematics education)—have positive effects.

At the end of reading these articles, I was left with a picture of what the future teacher should know and be able to do. Yes, future teachers should have a liberal education, but it was not clear where they would get it or what it might consist of. Yes, future teachers need a certain foundation of pedagogical content knowledge so that they can know how to teach what they know to the children in their care. And yes, it would be best if all future teachers were bright and well-educated. I was not persuaded—at least not by the evidence in the Kennedy research study—that future teachers need an advanced degree in education.

These provocative articles seem to me to be complementary, but they leave questions hanging. What is the liberal education that our future teachers need? Where should they get it? Do future mathematics teachers need to study literature and history as well as mathematics? How can the profession attract greater numbers of bright, well-educated people to its ranks, not just for a two-year experience, but for a professional commitment? Do current state requirements for pedagogical courses enhance teachers’ capacity or are they excessive? Are these requirements actually a deterrent to recruiting bright, well-educated college graduates to teaching? Should these state requirements be reviewed to make sure that they are infused with content knowledge as well as pedagogy?

We are left at the end of the discussion, as I see it, back at the place where William Learned and William Bagley left off. They thought that teacher education would become truly professional, that it might eventually become a post-baccalaureate professional study, akin to the study of law and medicine. That it did not may be seen either as a cause or an effect of the lesser status of teaching as a profession.

One can only dream of what a Learned School of Education might be in the twenty-first century. An institution where future teachers become masters of their craft; where they learn the best ways to teach their subjects; where every course is infused with the ideals of liberal education; where there is no distinction made between what to teach and how to teach it; where the entire institution is organized to attract, prepare, and educate the best teachers in the land.

In my imagination, school districts would vie for the graduates of such an institution, indeed would offer bonuses to attract them. If this seems utopian, it is because pedagogy never became what Learned and Bagley believed it must. It was marginalized for reasons partly of its own making. It did not develop a research-based, scientific approach to its work. The pedagogical individualism that reigned in pedagogical circles during the 1920s was one cause of its self-imposed isolation. The periodic need for vast numbers of new teachers, regardless of qualifications, was another. There were others as well. Whatever the reason, education never achieved the professional status that it needed and deserved.

As more and more states adopt alternative routes into teaching, this is a propitious time for teacher educators to think about these issues and to begin to reconsider the professional preparation of future teachers.

NOTE

63  Knowledge for teaching

What do we know?

Linda Darling-Hammond
Stanford University

In her thoughtful introduction to this section, Mary Kennedy identifies two dimensions of the long-standing debates over teacher education: One has to do with whether teachers benefit from specific preparation for teaching or need only a strong liberal education; the other has to do with the extent to which teachers benefit from specific courses in, for example, subject matter or teaching methods. She points out that views about what teachers need are generally framed in either/or terms: more of one kind of preparation means less of another, and notes the worry that “bright, liberally-inclined young people” might not choose teaching careers “because such people are not interested in vocational courses” or that such courses might take time away from acquiring more content.

WHAT ARE THE ISSUES THAT DRIVE THE DEBATE?

The relative merits of different kinds of coursework for teachers are certainly contended within the academy as well as in policy circles. Yet, the recurring arguments over teacher education and certification have their roots in much larger societal issues having to do with the role of education and teaching in society, the governance of educational decision making, and the costs and purposes of public education. Among these deep-seated disagreements are whether teaching should be treated as a profession, with the higher salaries and greater decision making authority for teachers this implies; whether education should be regarded as a public good available to all on equal terms, with the reallocations of resources that would accompany such a view; and—perhaps most contentious—who should decide what is taught and how. Resolving empirical questions about the utility of specific courses or programs of study is unlikely to settle these larger questions.

Frank Murray provides vivid examples of some of the things that teachers need to know beyond the liberal arts and subject matter content if they are to teach effectively. His illustrations are buttressed by exhaustive reviews of contemporary research on teaching and learning recently compiled by the National Research Council (Bransford et al., 1999) and the National Academy of Education (Darling-Hammond & Bransford, 2005). However, if teaching were to be regarded as a profession, with expectations that teachers master the kinds of knowledge these reports highlight, the question would shift from whether prospective teachers should study content or pedagogy within a short period of undergraduate education to how they should be enabled to study both and the intersections between them, with implications for the incentives needed to enable this more extensive preparation.

Indeed, “bright, liberally-inclined young people” seem plenty willing to engage in extensive vocational coursework for professions like law, medicine, engineering, and architecture. And in a number of other countries, like Australia, Finland, France, Germany,
New Zealand, Norway, and Taiwan, top candidates are eager to undertake the two to three years of graduate level teacher education that follow the one or two disciplinary majors they have already completed at the undergraduate level. The issue is not whether these teacher education courses are vocational but whether they open the door to a well-respected, well-compensated occupation that demands such study. It may not hurt that these extensive programs of teacher education are often completely subsidized by the state on the theory that society benefits when all teachers are well-prepared with strong subject matter and pedagogical training.

Teaching has failed to achieve professional status in the United States as much because low standards enable smaller investments in education, as because empirical evidence is unclear about the relative value of different kinds of coursework. The option of lowering standards for entry into teaching when salaries and working conditions are inadequate to bolster supply—especially in districts where poor and minority students attend school—reduces pressures for education spending and supports the current unequal allocation of resources (Darling-Hammond, 2004). Those interested in maintaining low cost teacher education and the unfettered hiring of untrained teachers have also argued against school funding reforms that would enable equal access to fully-prepared teachers and create larger investments in public education, particularly in poor urban and rural areas (e.g. Hanushek, 1996, 2000; Podgursky, 2000).

While opponents of teacher education often argue for recruiting bright people into teaching (and who could disagree with that?), their proposals do not offer incentives for attracting talented individuals into the occupation other than the removal of preparation requirements. While they present the removal of teacher education “barriers” as an attraction to teaching, evidence suggests that lack of preparation actually contributes to high attrition rates (Darling-Hammond & Sykes, 2003) and thereby becomes a disincentive to long-term teaching commitments and to the creation of a stable, high ability teaching force.

These same critics of teacher education often object to what is seen as its progressive ideology—for example, approaches that consider multiple intelligences or multicultural education, and pedagogies that emphasize critical thinking, comprehension, and problem solving, such as “whole language” instruction in reading (caricatured as a method “in which the teacher stands by while the student tries to guess what the word is”) or inquiry-oriented approaches in mathematics (described as “wasting time” when students must try to discover mathematical ideas that are already known) (Ballou & Podgursky, 1999, p. 41). At root here are issues about what will be taught in public schools and who will decide. To the extent that teachers are untainted by education schools, it is thought, they will be less likely to support these kinds of wrong-headed ideas. And to the extent that teaching is a high-turnover occupation whose members have little shared knowledge of learning and teaching, it is less likely that a legitimate claim to professionalism giving teachers greater voice in curriculum decisions will emerge.

These much larger philosophical, financial, and political issues are the ones that ultimately drive the debate on teacher education. It is no coincidence that the issues of whether teacher education matters and whether teacher certification should be required are at the heart of school funding litigation in many states where unqualified teachers are hired
in the under-resourced, lower-paying districts that serve the most disadvantaged students. Similarly, teacher education is regularly implicated in the great curriculum wars that are waged across the country. Readings of the research on teacher education are thus informed by the strongly held views of proponents and opponents of teacher professionalism, a well-financed and equitable public education system, and distinctive views of educational purposes.

WHAT DOES RESEARCH SAY ABOUT HOW TEACHER EDUCATION MATTERS?

Recent reviews of research have concluded that the weight of the evidence suggests that teachers who have more complete preparation are better rated and more effective than those who do not have this preparation, finding the evidence for the value of additional pedagogical training is at least as strong as for subject matter (Darling-Hammond, 2000; Wilson et al., 2001).

Kennedy, Ahn, and Choi seek to quantify one aspect of this question by examining the coefficients associated with different amounts of subject matter or pedagogical coursework in studies that have sought to predict individual student achievement gains in mathematics. Their chapter offers some interesting findings about the relative magnitude and direction of the influences of specific coursework and majors, which appear largely mixed. The strategy, if further refined, could be a potentially useful one. However, as implemented, it does not help us clarify the value-added effects of different kinds of teacher education, because the analysis does not report or interpret the set of teacher qualifications variables in each study, taking account of what is controlled in each model.

Evaluating effects: the need to disentangle preparation measures

Although the chapter provides a very useful treatment of the importance of examining statistical controls in studies, its later discussion of studies does not discuss their models or report on the other qualifications variables controlled in the estimates. The authors do not discuss the fact that the coefficient on a given variable is importantly related to the other qualifications already considered in that model. So, for example, if individual courses in mathematics are considered after mathematics majors have been controlled, the coursework coefficient will be likely to be much smaller than it would be in a model that did not include the major as a variable as well. The variance claimed by one qualifications measure will be offset by other related measures, and can cause a given variable to have a smaller coefficient if the underlying construct of interest has already been well represented in the model. In addition, since certification status includes many of the subcomponents of traditional teacher education (including subject matter and pedagogical requirements as well as tests of verbal and basic skills), its presence or absence in a given model will influence the size of other measures. Without this information it is difficult to meaningfully interpret and compare the findings of the studies on single measures of teacher preparation.

A more helpful kind of analysis is one that weighs and balances a set of qualifications variables in light of one another, as Goldhaber and Brewer (2000) did in their analysis of the effects of teacher qualifications on student achievement gains in math and science. The authors noted, for example, that

having a teacher with a standard certification in mathematics rather than a private
school certification or a certification out of subject results in at least a 1.3 point increase in the mathematics test. This is equivalent to about 10 percent of the standard deviation on the 12th grade test, a little more than the impact of having a teacher with a BA and MA in mathematics.

(p. 139)

In this case, the study included both majors and certification status, so the effect of each is estimated independent of the effect of the other. The fact that the study found a significant effect of certification status in mathematics even after controlling for whether teachers had a degree in their field (and certified teachers were more likely to have a major in the field) suggests that the knowledge represented by the certification variable has an influence above and beyond the influence of content knowledge.

Evaluating teacher effectiveness: “compared to what?”

Similarly, it is important to know whether preparation variables are controlled when comparing teachers with different background characteristics, such as the Teach for America candidates Kennedy, Ahn, and Choi examine as evidence for the “bright person” hypothesis. Early in their paper, Kennedy and colleagues write that “comparisons of TFA teachers and regularly certified teachers . . . offer us another way to test the bright, well-educated person hypothesis.” However, when they summarize studies that have examined TFA they ignore the findings that compare TFA teachers to certified teachers. In two of the studies they mention, which found evidence that TFA recruits’ students achieved comparable (in reading) or better (in math) gains in student learning when compared to other teachers (Raymond et al., 2001; Decker et al., 2004), the comparison group teachers were less likely to be prepared and certified than the TFA teachers. Most of the TFA teachers had had to enter a teacher education program when hired and became certified in the first two or three years of teaching if they stayed. Neither of these studies explicitly compared TFA teachers to teachers with standard training and certification, controlling for other student, teacher, and school variables.

The third study did look at certification (Darling-Hammond et al., 2005), but Kennedy and colleagues do not report its central findings. Looking at student achievement gains on six different reading and mathematics tests over a six-year period, this study found that certified teachers consistently produced stronger student achievement gains than did uncertified teachers of similar experience levels working in similar schools, including uncertified TFA recruits. On five of the six tests, the negative effect of having an uncertified TFA teacher was greater than the negative effect of having another uncertified teacher, depressing student achievement by up to three months annually compared to a fully certified teacher. The negative effects of TFA recruits were generally larger in reading than in mathematics. Similarly, a recent study in New York City found that beginning TFA teachers, along with other alternative pathway teachers, had a strong negative effect on student achievement in reading in the elementary grades relative to beginners from traditional teacher education programs; in mathematics, the effects were mixed (Boyd et al., 2005).

Like the other studies, Darling-Hammond and colleagues found that in three of the six years TFA teachers were more qualified than comparison teachers in Houston. In these years only, TFA teachers appeared to be as effective as other teachers when certification was not controlled. However, as the proportion of fully certified teachers in Houston grew over the years in our study, and as the proportion of TFA teachers who were certified declined, the observed effects of TFA teachers relative to other teachers became
increasingly negative. Thus, we found that interpreting the relative influence of TFA teachers on student achievement depended on knowing about the characteristics of the comparison group of teachers. The relative effectiveness of any group of teachers must be evaluated in a specific context at a particular point in time, with close understanding of the qualifications and characteristics of the comparison groups of teachers employed in that same setting at that point in time.

Thus, the “bright person” hypothesis appears to hold up only in the instances where untrained “bright person” recruits are compared to other untrained entrants, without taking preparation into account. It appears that general academic ability does not offset the need for professional training or render it irrelevant. While uncertified TFA recruits were less effective than certified beginning teachers in teaching both reading and math, they appeared to benefit from preparation, and were as effective as others on most measures when they became certified. On one of the six test measures—the TAAS in mathematics—certified TFA recruits appeared more effective than other certified teachers. This finding—and a similar finding from the recent study of teacher education pathways in New York (that experienced TFA recruits had a positive effect on student mathematics gains by their third year of practice, relative to traditionally trained teachers, though they continued to have a negative effect on reading scores)—might be attributed to the strong liberal arts background of TFA teachers. It is plausible that candidates who have attended selective colleges may have a stronger basic mathematics background in high school and college than the average elementary teaching candidate, and that this strength in prior knowledge might translate into greater effectiveness when teaching skills have been mastered.

WHAT CAN (AND SHOULD) TEACHER EDUCATION DO?

Even if one were to accept that teacher education courses have some value, including for “bright persons” entering teaching, there is no dispute that there is a wide range of quality among teacher education programs. As the chapters in this section point out, the movement of teacher education from normal schools to the university has created serious dilemmas for both the identity of teacher education and the development of those teaching skills that require intensive, long-term engagement with practice. Murray notes that “the curricular content that is in place . . . is typically not clearly connected to the educational needs of children and adolescents.” His suggestion for a kind of backward mapping from the needs of children to the content of preparation for teachers is exactly the process undertaken by the National Academy of Education’s Committee on Teacher Education in its four-year process of developing recommendations for a teacher education curriculum based on what we have come to know about how children learn, as well as what we have learned about how teachers teach (Darling-Hammond and Bransford, 2005).

The Committee’s work identified key concepts within several domains of knowledge that are critical for teachers:

- knowledge of learners and how they learn and develop within social contexts, including knowledge of language development;
- understanding of curriculum content and goals, including the subject matter and skills to be taught in light of disciplinary demands, student needs, and the social purposes of education; and
- understanding of and skills for teaching, including content pedagogical knowledge and knowledge for teaching diverse learners, as these are informed by an understanding of assessment and of how to manage a productive classroom.
The Academy’s proposals go beyond the questions raised here about teacher education coursework to argue that the clinical experiences embedded in and linked to coursework are equally important. Indeed, learning to teach requires that new teachers not only learn to “think like a teacher” but also to “act as a teacher”—posing what Mary Kennedy (1999) has termed “the problem of enactment.” Teachers need not only to understand but also to do a wide variety of things, many of them simultaneously. One of the perennial dilemmas of teacher education is how to integrate theoretically-based knowledge that has traditionally been taught in university classrooms with the experience-based knowledge that has traditionally been located in the practice of teachers and the realities of classrooms and schools. The challenge may be less one of adding on more courses or sharpening their content in the abstract and more one of connecting them appropriately to the problems of practice. This is where the absorption of normal schools into universities—and the predominant focus on coursework with little attention to strong clinical opportunities—weakened many teacher education programs. Traditional teacher education has often had students taking batches of front-loaded coursework in isolation from practice and then adding a short dollop of student teaching to the end of the program—often in classrooms that did not model the strategies that had previously been described in abstraction.

In order to help teachers enact good practices, close connections between theory and practice, coursework and clinical work are necessary, along with access to high-quality modeling, practical strategies, useful tools, and repeated opportunities for practice. Many teacher educators have argued that novices who have experience in classrooms are more prepared to make sense of the ideas addressed in their academic work and that student teachers understand both theory and practice differently if they take coursework concurrently with fieldwork. A growing body of research confirms this belief, finding that teachers-in-training who participate in fieldwork with coursework are better able to apply concepts they are learning in their coursework and to support student learning (Darling-Hammond & Bransford, 2005, p. 398).

Similarly, a study examining seven exemplary teacher education programs that produce graduates who are extraordinarily well-prepared from their first days in the classroom found that all of these programs had built a more powerful clinical curriculum than is typically found in teacher education (Darling-Hammond et al., 2006). Candidates spend extensive time in the field throughout the entire program—and complete many kinds of performance assessments and analyses of teaching and learning—examining and applying the concepts and strategies they are simultaneously learning about in their courses alongside teachers who can show them how to teach in ways that are responsive to learners. These programs typically require at least a full year of student teaching under the direct supervision of one or more teachers who model expert practice with students who have a wide range of learning needs, with the candidate gradually assuming more independent responsibility for teaching. This allows prospective teachers to grow “roots” on their practice, which is especially important if they are going to learn to teach in ways that are attentive to learning and require diagnosis, adaptations to learners’ needs, intensive assessment and planning, and a complex repertoire of practices, judiciously applied.

It has often been the lack of this kind of serious clinical work in schools of education that has led some to view them as irrelevant, and it may be that the lack of connections between coursework and clinical work in many programs render the coursework much less powerful and productive than might otherwise be the case.

Finally, as we consider the nature of knowledge for teaching, we should contemplate the ways in which knowledge for practice is to be used. Murray notes that “competing practices, like whole word and phonics instruction in initial reading methods, have
reasonable levels of current scholarly support and adherents,” suggesting that, without disposition of these kinds of questions and clarity about “codes of good practice,” teaching is “behind” other professions. However, other professions also have many potentially competing techniques supported by research—and often try to reconcile these viewpoints by exploring whether there are circumstances in which one is to be preferred to the other or how they may be used in combination for particular purposes, rather than seeking to land solely on a single answer. Consider the recent debates and competing studies in medicine about issues ranging from hormone replacement therapy to very distinctive schools of treatment for a range of cancers. Doctors are expected to evaluate the evidence and make judgments based on their view of the reach and constraints of the research and the needs of individual clients with different situations at different points in time. Indeed, the goal of professional education in these other fields is not the acquisition of a body of settled knowledge but the understanding of underlying principles, the ability to read and interpret continually emerging research, and the diagnostic skill to assess when various strategies are likely to be most useful.

Similarly, rather than learning the pre-determined right answers to questions about strategy (or learning to implement one or another prescribed orthodoxy), teachers need highly refined knowledge and skills for assessing pupil learning, and they need a wide repertoire of practices—along with the knowledge to know when to use different strategies for different purposes. Rather than being subject to the pendulum swings of polarized teaching policies that rest on simplistic ideas of best practice—“whole language” vs. “phonics,” for example, or inquiry learning vs. direct instruction—research suggests that teachers need to know how and when to use a range of practices—often in different combinations—to accomplish their goals with different students in different contexts. Teaching will not wait to become a profession until a larger basket of right answers has been assembled and incorporated into their training. Teachers will be armed with useful professional knowledge when they are given the kind of preparation, as Weiland notes, that enables them to respond to Higgins invitation to be intellectuals themselves—weighing and balancing the appropriateness of practical actions in light of what is suggested in theory and what is consistent with the needs of individual children. That blend of analytic thinking, borne of liberal education at the intersection of content and pedagogy, and of clinical insight, borne of thoughtful work in classrooms connected to a practical, professional knowledge base, will arm teachers with the knowledge they need to become increasingly successful.

REFERENCES

For the sake of clarity—but recognizing that it requires foregoing potentially instructive nuance—I want to suggest that two competing perspectives dominate thought on the relationship of teacher education and the education of teachers.

One perspective holds that there is a definable body of knowledge, thought, and practice that teachers need to possess. Regarding teaching as a “profession” in which practitioners are obliged to have mastered essential skills prior to entry, proponents deem teacher education to be essential and invaluable for aspiring teachers. These “essentialists” argue that all teachers need to have completed an appropriate program of “teacher education” in the course of their training. There are some in this camp who would go even further, suggesting that preparation should also help teachers cultivate the “dispositions” and worldviews deemed necessary for effective practice.

The second perspective is skeptical of claims that there is an understood body of knowledge that responsible professionals must master. This camp tends to be even more wary of the notion that there are identified dispositions or values necessary for effective teaching and learning. Consequently, members of the “elective” camp—while acknowledging that teacher instruction can be very useful for some teachers, at some times, when provided by certain instructors or institutions—doubt that formal teacher education is essential to the education of teachers.

There is a third, peripheral school of thought, composed of a handful of vocal education school critics who believe that teacher education is an intellectually corrupt enterprise dominated by progressive ideologues, and that formal teacher education should be dismantled. However, because they are engaged more in a cultural critique than in a debate over the nature and role of teacher education, I will set them aside for the purpose of this essay.

What may seem a modest disagreement between the “essentialists” and the “electivists” grows impassioned because the stakes are larger than they may at first appear. In addition to questions of funding, jobs, and political influence, the status of teaching as a conventional “profession” hinges on the answer. For those who work in schooling or teacher education, this makes the stakes very high indeed. There is a natural inclination to insist that one’s work requires careful preparation and cloak it in the garb of “professionalism,” if possible. For these reasons, the “essentialist” camp tends to find much sympathy among educators and education professors, all of whom have good reason to embrace arguments that elevate their profession’s import. Unsurprisingly, those of the “electivist” persuasion find a much cooler reception in those quarters. For these reasons, the dispute frequently pits those inside the world of teaching and teacher preparation against those outside this world.

However, the two camps do not break down neatly along ideological or partisan lines. For instance, some groups frequently perceived as hostile to conventional teacher
education—such as Teach For America and “conservative” proponents of “scientifically-based research”—are amenable to the claim that there are things teachers must believe or need to know before entering the classroom. In other words, they are members of the “essentialist” camp; their disagreement with many in that camp is more about what those things are, how to identify them, and what kind of formal programs should teach them.

To varying degrees, members of the “essentialist” and “electivist” camps disagree about the skills and knowledge that aspiring teachers need, how to cultivate good teaching, what effect various licensing requirements have on the quality of applicants, and what the evidence says about these questions. Ultimately, the merits of the two perspectives turn on a variety of claims. Because supporters tend to put these forward on both normative and empirical grounds, sorting out the arguments requires distinguishing the mingled claims.

Moreover, the empirical basis for making strong claims regarding “what we know” about the value of teacher education is extremely tenuous. In their review of the research, Kennedy, Ahn and Choi are careful to acknowledge the data limitations, self-selection issues, and related caveats that warrant caution in judging the utility of preparation based on the handful of studies that meet even minimal requirements for rigor and validity. For that reason, it was somewhat surprising to see them seemingly brush away this sensible caution in concluding that the evidence shows even modest value in taking education and math education courses in the area of math instruction. While it’s not unlikely that additional professional training may yield some benefits—one would be astounded if teacher education was never beneficial—it seems rash to draw such a conclusion based on the existing evidence.

In short, while various scholars and practitioners can frequently judge an existing body of research differently, I suggest that it is very difficult to justify the “essentialist” position on empirical grounds. Consequently, it’s worth carefully considering the assertions underlying the “essentialist” position. In reading the essays I was asked to respond to, I was struck by four key “essentialist” claims deserving of scrutiny. And because the “electivist” position merely suggests that the significance of such preparation is contingent, the burden of proof in this discourse lies with those who claim that teacher education is essential. If teacher preparation is only helpful in some cases, for some people, when teaching some subjects, or in some schools, then it is difficult to prove that it is essential.

The first “essentialist” claim, voiced by Frank Murray, is that absent professional training, teachers will have low expectations for students. In making this point, Murray quotes two studies, both more than two decades old, and he goes on to suggest that “natural” teachers (those who have not benefited from teacher education) will systematically treat disadvantaged pupils in ways that inhibit academic growth. But he never explains just why or how it is that teacher education serves to raise expectations. In a familiar refrain, Murray also suggests that today’s teacher education programs may not have the desired effect, but this is a fixable glitch rather than a real challenge to the “essentialist” position.

There is, however, cause to believe that teachers who complete teacher education are among those whose expectations for students, including poor and minority students, are disappointingly low. For instance, a 2005 survey of Teach For America (TFA) teachers—almost none of whom had completed a recognizable course of teacher education—found that they had demanding standards for their students, themselves, and their schools. Similarly, some schools that have relied on large numbers of teachers without formal preparation—such as the KIPP Academies and many parochial schools—have seen disadvantaged students make achievement gains that dramatically exceed those posted by
students with formally trained teachers. Now, the significance of such anecdotal claims is primarily illustrative, so I do not intend to overstate their particular import. Rather, I mean to suggest that the argument in general—that teacher education infuses future teachers with a burning sense of mission or a passion for demanding standards—seems to run in the face of much experience.

A second “essentialist” claim is that we have a reasonably coherent idea of what teachers need to know or be able to do, and that any aspiring professional ought to be educated accordingly. But in reality, a close look at the state of research-based knowledge on instruction, pedagogy, and learning suggests that, as a general rule, we know very little about what teachers need to know or what skills will make them more effective. While today’s teacher educators claim to have assembled a body of knowledge equal to the task, these same claims have been made for decades. Consider, just to take one example, the award-winning 1999 Harvard University Press book, *Teaching in America*, penned by education scholars Gerald Grant and Christine E. Murray. In the volume, Grant and Murray identify five “essential acts” that should be analyzed and taught: listening with care; motivating the student; modeling caring by hearing and responding to the pain of others and creating a sense of security in the classroom; evaluating by clarifying, coaching, advising, and deciding on appropriate challenges for individual students; and reflecting and renewing. The authors never even addressed how these five “essential acts” are to be taught, much less how to determine whether a teacher has mastered them. Under scrutiny, claims about research-based knowledge and established instructional or pedagogical methods typically prove to be a stew of theory, intuition, anecdote, and inconclusive findings.

Third, “essentialists” frequently argue that effective teachers need to be educated on the subjects and effects of “sexism,” “racism,” “classism,” “bilingualism,” “heterosexism,” “white privilege,” the “language of oppression,” and other, related, biases. The National Council for the Accreditation of Teacher Education has made the cultivation of appropriate dispositions and the promotion of “diversity” central to its standards for teacher education. But there is no unanimity on the importance or effectiveness of such instruction. Skeptics question the pedagogical or instructional utility of such concepts, noting the lack of evidence supporting claims that teachers educated in these modes of thought are more effective by any discernible metric.

Leading voices in teacher preparation, including Nel Noddings, the president of the National Academy of Education, have unapologetically argued that teacher education is about championing certain values—without suggesting that there is evidence that these values enhance teaching and learning. As Marilyn Cochran-Smith (2004), former president of the American Educational Research Association (AERA) has argued, “Education (and teacher education) are social institutions that pose moral, ethical, social, philosophical, and ideological questions. It is wrong-headed—and dangerous—to treat these questions as if they were value neutral and ideology free” (p. 6). Gloria Ladson-Billings, another former AERA president, has said that she believes good teaching entails promoting an “anti-racist, anti-sexist, anti-homophobic . . . anti-oppressive social justice pedagogy” (in Kumashiro, 2004, p. xiv). The reality is that instruction in this area frequently amounts to advocacy of particular perspectives. Given the lack of evidence on the value of promoting certain perspectives, and the possibility that students with a variety of backgrounds and views may benefit from encountering teachers with heterogeneous beliefs, skeptics are dubious of the utility of this instruction.

A fourth claim, again eloquently advanced by Murray, is that untrained teachers are pedagogically unsophisticated and unable to construct the kinds of lessons or provide the kind of instruction that trained teachers can provide. For instance, Murray asserts that
untrained teachers are overly prone to “showing and telling” and devote too little attention to engaging students, cultivating student thinking, or addressing the full range of social and intellectual development. Of course, one problem with this argument is the scant evidence that teacher preparation has a profound or lasting impact on how teachers actually teach. Murray, for instance, is unable to present any evidence that those who have completed teacher education are more likely to utilize “dialectical” methods or are more likely to use them effectively.

The more fundamental question, however, may be whether emphasizing concrete mastery and factual knowledge is necessarily bad for students. There is certainly a school of thought that schools ought to deemphasize teacher-centered instruction and employ pedagogies based on discovery, invention, and collaboration; but it is a mistake to suggest that this is rooted in a body of established, uncontested knowledge rather than personal judgment. Moreover, exactly when “showing and telling” is excessive or inappropriate, as opposed to a useful component of disciplined instruction, is a subject of legitimate dispute. In short, it is not a settled matter that the pedagogical and instructional practices that Murray associates with teacher education graduates are more effective than those of teachers who have not received such an education.

Finally, a critical problem for the “essentialist” position is that even its leading proponents are generally critical of much contemporary teacher education—though they are quick to explain that its disappointments ought not tarnish the “essentialist” school of thought. Even staunch defenders of the “essentialist” position, including thoughtful scholars like Linda Darling-Hammond and Gary Sykes, concede that there are many teacher education programs that fail to embody the standards they have in mind. It may indeed be possible to imagine teacher education that could be integral to the education of teachers. However, decades of efforts have failed to realize that vision in more than a small number of the nation’s 1,300 preparation programs. As Lee Shulman (2005), president of the Carnegie Foundation for the Advancement of Teaching, argued in late 2005, we have not yet created a coherent system of teacher education in the United States. Shulman acidly observed,

Teacher education does not exist in the United States. There is so much variation among all programs in visions of good teaching, standards for admission, rigor of subject matter preparation, what is taught and what is learned, character of supervised clinical experience, and quality of evaluation that compared to any other academic profession, the sense of chaos is inescapable.

(p. 7)

There comes a point where persistent and widespread institutional failure ceases to be a question of implementation and gives cause for a fundamental rethinking of the institution. It’s at least worth asking, if this is all we have to show after 150 years of efforts and five decades of sustained institution building, whether there might not be something about teacher education that will almost inevitably frustrate “essentialist” efforts to formalize and institutionalize its delivery.

It is certainly possible to imagine circumstances under which both camps might regard teacher education as more critical for the proper education of teachers. If educational researchers were to make meaningful strides in identifying practices that consistently deliver educational benefits for children, aspiring educators should clearly be expected to know and be able to apply the relevant findings. As research proceeds, it increasingly yields important insights into cognition, learning, and brain development. If teacher
education begins to teach this new knowledge in a disciplined and relevant manner, then it may indeed come to be essential for educating teachers. Of course, teacher education under those conditions may look very differently than it looks today. Importantly, there’s no guarantee that those academics that have fought so hard to preserve teacher education in its contemporary shape will be pleased with the form it takes under such circumstances, or even that they will be equipped to provide the requisite instruction. In the meantime, teacher education remains a nonessential but potentially useful exercise that can contribute to the education of some teachers, at some times, and for some purposes.
